Abstract

Objectives: This study was designed to determine the morphometric and histological changes of the wall of the thoracic aorta in high salt-fed adult Wistar rats and the possible ameliorative effects of aqueous extract of garlic (*Allium sativum*).

Methods: Twenty-five healthy female Wistar rats weighing 130–180 g were randomly assigned into five groups of five rats each (Groups A, B, C, D and E). Rats in Group A were fed with standard laboratory pellets, while Groups B, C, D and E were fed on the high-salt diet for five weeks. Thereafter, daily administration of 50 mg/kg, 100 mg/kg and 150 mg/kg of the garlic extract were giving orally to Groups C, D and E, respectively for 3 weeks while rats in Groups A and B were administered distilled water. The thoracic part of descending aorta at the level of (T6–T7) was excised for histological studies. Paraffin sections were stained with haematoxylin and eosin, Masson’s trichrome and Verhoeff-Van Gieson stains. One-way ANOVA was used to analyze data, followed by Student-Newman-Keuls (SNK) test for multiple comparisons.

Results: High salt diet causes significant histomorphological changes on aorta of rats as evidenced by increase in tunica intima, media and adventitia of the aortic wall and decrease in luminal diameter; these findings were reversed by aqueous garlic extract administration.

Conclusion: High salt diet increased the thickness of aortic wall and decreased luminal diameter which were significantly reversed by oral administration of garlic extract.

Introduction

Garlic is reported to have prophylactic and therapeutic properties in conditions such as microbial infections, thrombosis, hypertension, hyperglycemia, hyperlipidemia, cancer, and thrombosis. The contents of garlic extract include sulfur active compounds mainly in the form of cysteine derivatives such as S-alkyl cysteine and sulfoxides, which are decomposed to thiosulfinates and polysulfides by allinase on extraction. Aqueous extract of garlic (*Allium sativum*) prevents platelet aggregation and oxidative stress. The cardioprotective effects of garlic are related to its antiatherogenic properties, cholesterol lowering effect and improvement of vascular function.

High salt intake leads to increased peripheral vascular resistance; a variety of factors appear to contribute to an augmented vascular reactivity to α-adrenoceptor agonists reported in laboratory animals. Increased generation of reactive oxygen species and a down-regulation of nitric
oxide synthase (NOS) subtypes are observed with high salt intake.\[11,12\] In spontaneously hypertensive rats and Dahl salt-sensitive rats, high salt intake produced impaired endothelium dependent relaxation.\[9,13,14\]

A high salt intake also leads to changes in the renin–angiotensin system. The expression of angiotensin type 1 (AT1) receptors is altered in high salt diet in arteries of Dahl salt-sensitive or resistant rats and Wistar rats.\[15–17\] This study investigated the effect of aqueous garlic extract as an alternative therapeutic method, studying the morphometric and histological changes of the wall of the thoracic aorta on high salt-fed adult Wistar rats.

**Materials and Methods**

**Animal care and management**
Twenty-five healthy female Wistar rats (130–180 g) from the Animal Holding of College of Health Sciences, Obafemi Awolowo University Ile-Ife were used for this study. The rats were randomly assigned into 5 groups of 5 rats each (Groups A, B, C, D and E). They were maintained on standard laboratory rat pellet before the commencement of the experiment and water was provided *ad libitum*.

**Plant material and preparation of extract**
Clove of garlic bulb were procured from Sabo market in Ile-Ife and identified by a taxonomist in the Department of Botany, Obafemi Awolowo University, Ile-Ife. They were weighed and then blended with water. Cloves were filtered into a conical flask using filter paper and a funnel to produce a clear juice. Then, the filtrate was freeze-dried using a lyophilizer and stored in a desiccator. An aliquot portion of the crude extract residue was dissolved in distilled water and administered on each day of the experiment.\[18\]

**Preparation of high salt diet**
High salt diet containing 8% sodium chloride was prepared specially by replacing 0.3% sodium chloride-containing standard diet with 8% sodium chloride.\[19,20\]

**Animal treatment**
Group A was the control, Group B was negative control, while Groups C, D and E were the test groups. Rats in Group A were fed with standard laboratory pellets, while Groups B, C, D and E were fed on the high-salt diet for five weeks. Thereafter, daily administration of 50 mg/kg, 100 mg/kg and 150 mg/kg of the garlic extract were giving orally to Groups C, D and E, respectively for 3 weeks, while rats in Group B was left untreated for the same period. The extract solution was administered orally, using oral cannula, and the duration of the experiment was 8 weeks.

**Sacrifice of animals**
At the end of the experiment, the rats were sacrificed under ketamine anesthesia. The thoracic part of descending aorta at the level of T6–T7 were excised and weighed.

**Histological techniques**
The excised aorta was fixed in neutral buffered formalin for 24 hours, and processed using paraffin wax embedding method. Sections of 5 µm thickness were cut from the paraffin embedded tissues and stained with haematoxylin and eosin stain to demonstrate the general histoearchitecture of the aorta.\[21\] Masson’s trichrome stain was used to demonstrate collagen fibers in the descending thoracic aorta, while Verhoeff-Van Gieson stain was used to demonstrate elastic fibers in the thoracic aorta.\[22,23]\n
**Photomicrography**
Stained sections were viewed under a Leica DM750 microscope (Leica Microsystems, Heerbrugg, Switzerland) with digital camera attached (Leica ICC50) and digital photomicrographs were taken at various magnifications. Photomicrographs of stained sections were imported onto the ImageJ version 1.48 (NIH, Bethesda, MD, USA) software for histomorphometric analysis of tunica intima, media and adventitia and lumen diameter.

**Quantification of staining intensity**
Image analysis and processing for Java (ImageJ), was used to analyze and quantify Masson’s trichrome and Verhoeff-Van Gieson staining intensity. Imported RGB images were converted to grayscale images on ImageJ. The software quantifies staining intensity by measuring the pixel value of each pixel in grayscale images following threshold of areas of staining activity and converting the pixel value to brightness value or gray value, in a scale of 0 to 255 from less brighter (that is more intensity) to more brighter (that is less intensity).

**Statistical analysis**
One-way ANOVA was used to analyze data, followed by Student-Newman-Keuls (SNK) test for multiple comparisons. GraphPad Prism 5 (Version 5.03; Graphpad Software Inc., San Diego, CA) was the statistical package used for data analysis. Statistically significant difference was set at p<0.05.
Results

There was a significant difference in thickness of the tunica media of the aortic wall across all experimental groups ($F_{4, 20}=530.8; p<0.05$). Post hoc analysis showed that thickness of the tunica media of the aortic wall of high salt-fed group was significantly increased compared to the control group ($p<0.05$). The thickness of the tunica media of the aortic wall which was increased by the high salt diet was significantly and dose dependently reversed by garlic extract administration (Figure 1). There was also a significant difference in thickness of the tunica adventitia of the aortic wall across all experimental groups ($F_{4, 20}=13.49; p<0.05$). Thickness of the tunica adventitia of aortic wall of high salt-fed group was significantly higher than the control group ($p<0.05$). The thickness of the tunica adventitia of aortic wall which was increased by the high salt diet was significantly and dose dependently reversed by garlic extract (Figure 2). Significant difference in thickness of the tunica intima of aortic wall was observed across all experimental groups ($F_{4, 20}=4.321; p<0.05$). Thickness in tunica intima of the aortic wall of high salt-fed group was significantly higher than the control group ($p<0.05$). This effect was sig-

Significantly and dose dependently reversed by garlic extract administration (Figure 3). The luminal diameter of aorta in Group B was significantly lower than the control group (p<0.05); this was also significantly and dose dependently reversed by aqueous garlic extract in Groups D and E (Figure 4).

Figure 5a shows the photomicrograph of the section of a descending aorta in the control group revealing the three basic layers of the blood vessel, the tunica intima, tunica media and the tunica adventitia. In the high salt-fed group, tunica media was thicker compared to the control, but with fewer stained nuclei comparatively (Figure 5b). Figure 5c shows the thicker wall. Figures 5d and 5e show the three layers with similar architecture as control. There was an increase of collagen fibers in histological sections from aorta of the rats (Figures 6 and 7). The distribution of elastic fibers (black) in Figures 8b and 8c were reduced when compared with Figure 8a (control group). In Figures 8d and 8e, there was significant improvement in the deposition of elastic fibers. This was also observed in analysis of the area of elastic fibers (Figure 9).

Discussion

A morphometric and microanatomical study on the effects of aqueous garlic extract on aorta of high salt-fed adult Wistar rats was carried out in this study. It was observed that the tunica intima, media, adventitia and lumen diameter of the aorta were significantly higher in the high salt-fed group than the control group (p<0.05). This suggests that high salt diet resulted in hypertrophy of the aortic walls which are in accordance with the earlier studies by
Ofem et al.\cite{24} and Adewole et al.\cite{25} Increasing evidence from multiple clinical studies showed that excess salt intake was associated to cardiovascular damage, independent of blood pressure.\cite{26} The pathophysiological mechanisms responsible for high salt diet–induced changes remains debatable.

In this study, the hypertrophy of the aortic walls caused by high salt diet and also the sparse distribution of elastic fibers in Figure 8b was an evidence of injury in that group, as sparsely distributed of elastic fibers reduced the tensile strength and elasticity of the vascular structures which could lead to rupture of the arterial wall.\cite{27} This morphological change was significantly ameliorated by the garlic extract.\cite{27} The impairment of aortic elastic properties in the present research may be due to the direct effect of the high salt diet on the aorta of the rats. The increased stiffness of the aorta was asso-

Aqueous extract of garlic administration alleviates high salt diet-induced changes in the aorta of adult Wistar rats

In addition, the increased thickness of the tunica media may be partly due to the increased medial smooth muscle cells observed in the high salt-fed group. The active ingredient in garlic extract is known as allicin (diallyl thiosulfinate) which is mainly an organosulfur that has been shown to inhibit renin-angiotensin-aldosterone system and prostaglandin synthesis.\cite{29} Garlic has been reported to exhibit potent angiotensin converting enzyme (ACE) inhibitory activity.\cite{30} The reduction in ACE activity results in reduction of plasma level of angiotensin II. Angiotensin II is also known to cause cardiovascular changes and sodium ion retention through stimulation of aldosterone release.\cite{31,32} Garlic extract-induced inhibition of ACE probably leads to reduction in angiotensin II, leading to decrease in adrenal production of aldosterone.\cite{33} The garlic extract-induced-reduc-

tation of plasma level of angiotensin II followed by natri-
and diuresis may be responsible for the reversal of the high salt-induced vascular and aortic wall hypertrophy reported with morphometric measurements in this study.

Conclusion
The results of this study indicated that high salt diet causes significant histomorphological changes on aorta of rats as evidenced by increase in tunica intima, media and adventitia of the aortic wall and decrease in luminal diameter; these findings were reversed by aqueous garlic extract administration. The restorative and ameliorative effects of garlic extract on high salt diet-induced changes in cardiovascular system are probably via inhibition of renin-angiotensin-aldosterone system.
