Application of Overfire Air Technology on an Example of a Steam Boiler PK-39 of the Aksu TPP (Kazakhstan)

A. Askarova, S. Bolegenova, V. Maximov, S. Bolegenova, Z. Gabitova, A. Yergaliyeva, A. Nugymanova, M. Beketayeva, Sh. Ospanova

Abstract— When burning any fossil fuels, one of the most harmful combustion products are nitrogen oxides NOx, which damage both the environment and human health in particular. Reduction of NOx emissions from fuel combustion at TPPs plays an important role in reducing the total level of nitrogen oxides NOx emitted into the atmosphere. One way to reduce the concentration of nitrogen oxides NOx is the stepwise combustion of the pulverized coal mixture, in particular the «Overfire Air» technology. The essence of this method is that the main volume of air is fed into the pulverized burners, and the rest of the air is further along the height of the torch through special nozzles. Structurally, the method of stepwise combustion of fuel can be carried out in boilers with a two-tier arrangement of burners along the height of the combustion chamber. In this case, practically no significant reconstruction of the boiler is required, which is associated with additional costs. In the present work, computational experiments on the use of modern overfire air technology (OFA) in the combustion chamber of the PK-39 boiler of the Aksu TPP were carried out and the fields of the main characteristics of heat and mass transfer, as well as the influence of the mass flow of the oxidant through the OFA injectors on the combustion process were obtained.

Index Terms— coal combustion, numerical simulation, overfire air technology.

I. INTRODUCTION

As of today, Kazakhstan is one of the states possessing a huge stock of hydrocarbons, which render essential influence on formation and a condition of the world energy market [1-3].

In the Republic of Kazakhstan, about 80% of the country’s energy supply comes from the production of electricity by 69 power plants, the main source of which is Kazakh coal [4-6].

The coal mining in Republic is carried out basically by the open way, which makes this type of solid fuel the cheapest, but low-grade (high ash content in its composition) in our country a source of energy [3,7-8]. At the same time, the coal of Kazakhstan possesses a number of advantages – small sulphur content of coals and a high volatiles content on a dry ash-free basis.

For the sustainable development of heat and power industry of the country in the near future, it is necessary to optimize the combustion of traditional energy fuel (Kazakh coal), to develop and implement clean energy technologies; to protect the environment from harmful dust and gas emissions and ensure the efficiency of power plants. One of the methods for reduction of NOx concentration is the overfire air technology – OFA.

Technological methods for suppressing the formation of nitrogen oxides are based on a reduction in the peak temperature and oxygen content in the active combustion zone, as well as in the formation in the combustion chamber of zones with a reducing medium, where the products of incomplete combustion, reacting with the formed nitric oxide, lead to the reduction of NOx to molecular nitrogen N2.

Thus, in the zone of active combustion, an oxygen-depleted and fuel-enriched combustion zone is formed. Due to the lack of air in this area, the average temperature is lower than in traditional combustion, which allows to reduce the amount of fuel and thermal nitrogen oxides. Further, above the level of the main burners, additional air is supplied through the tertiary air nozzles necessary for afterburning the products of incomplete combustion and an oxidizing medium is formed [9-10].

The most difficult step in realization of the OFA technology is to define the optimal location height and diameter of nozzles through which air will be supplied, and to find the best ratio of air supplying through the main burner and OFA-injectors. These characteristics depend on design of the boilers and the method of supplying fuel-air mixture [10-11].

To effectively implement this technology on an industrial boiler, the height of the OFA injectors should be chosen so that in the active combustion zone a complete burn-out of the fuel and its afterburning to the final combustion products are ensured, since incomplete mixing of fuel and oxidant can
increase underburning [12].

II. BASIC EQUATIONS OF HEAT AND MASS TRANSFER IN REACTIVE MEDIA

The computational experiment was carried out on the basis of the solution of the three-dimensional equations of convective heat and mass transfer taking into account the propagation of heat, thermal radiation, chemical reactions, and the multiphase nature of the medium. To describe the three-dimensional motion of reacting currents in the furnace chamber of the boiler PK-39, a system of differential equations [3,13-19] based on the control volume method [6, 18-20] is used:

- The conservation law of mass or the continuity equation

The ratio of the mass balance for control volume represents the continuity equation.

\[
\frac{\partial \rho}{\partial t} = -\frac{\partial (\rho u_j)}{\partial x_j}
\]  

(1)

- The conservation law of momentum or equation of motion

Momentum balance is based on the second law of Newton-momentum change of the liquid in the control volume is equal to the sum of all external (surface and efficient volume) forces attached to the control volume.

\[
\frac{\partial (\rho u_j)}{\partial t} + \frac{\partial (\rho u_j u_j)}{\partial x_j} = -\frac{\partial p}{\partial x_j} + \rho f_j + \frac{\partial}{\partial x_j} \left[ \mu \left( \frac{\partial u_j}{\partial x_j} + \frac{2}{3} \frac{\partial u_i}{\partial x_i} \right) \right]
\]  

(2)

- The conservation law of energy

The energy equation is based on the first law of thermodynamics.

\[
\frac{\partial (\rho h)}{\partial t} + \frac{\partial (\rho u_j h)}{\partial x_j} = \frac{\partial (\mu \frac{\partial h}{\partial x_j})}{\partial x_j} + S_h
\]  

(3)

- The conservation law of the components of the substance

In an isotropic medium consisting of \( \beta \) components, the components can move with different velocities \( u_i, \beta \). For the mass balance of the \( \beta \)-component of the medium it can be written:

\[
\frac{\partial (c_{\beta}p_{\beta})}{\partial t} + \frac{\partial (u_i c_{\beta}p_{\beta})}{\partial x_j} = \frac{\partial (\mu \frac{\partial c_{\beta}}{\partial x_j})}{\partial x_j} + p_{\beta} + S_{\beta}.
\]  

(4)

The combustion of coal dust in combustion chambers is turbulent, and in this connection, a standard k-ε model of turbulence was used to simulate turbulent viscosity and closure of the system [1,2,6,15]. The model includes

- The equation of transport of turbulent kinetic energy \( k \):

\[
\frac{\partial (\rho k)}{\partial t} + \frac{\partial (\rho u_j k)}{\partial x_j} = \frac{\partial}{\partial x_j} \left[ \mu_{\text{eff}} \frac{\partial k}{\partial x_j} \right] + p - \rho \cdot \varepsilon,
\]  

(5)

where \( p \) – turbulent kinetic energy production:

\[
P = \mu_{\text{turb}} \left( \frac{\partial u_j}{\partial x_j} + \frac{\partial u_i}{\partial x_i} \right) \frac{2}{3} \rho k \delta_{ij} \frac{\partial u_j}{\partial x_j}
\]  

(6)

The equation of dissipation of turbulent kinetic energy \( \varepsilon \):

\[
\frac{\partial (\rho \varepsilon)}{\partial t} = \frac{\partial}{\partial x_j} \left[ \frac{\mu_{\text{eff}}}{\sigma_{\varepsilon}} \frac{\partial \varepsilon}{\partial x_j} \right] + C_{\text{eq}} \frac{\varepsilon}{k} \rho C_{\varepsilon} \cdot \varepsilon \cdot \varepsilon + C_{\text{turb}} \frac{\varepsilon^2}{k} \rho \varepsilon.
\]  

(7)

where \( \varepsilon \) – transformation of the kinetic energy of the pulsating motion into internal energy (dissipation);

\( \sigma_{\varepsilon}, C_{\varepsilon} \) – the corresponding turbulent Prandtl numbers.

Considering the processes of heat exchange in technical reacting flows in combustion chambers, heat exchange by means of radiation makes the greatest contribution to total heat transfer. In the flame zone, the contribution of radiant heat exchange is up to 90% of the total heat transfer and even more [21]. In this regard, the simulation of heat transfer through radiation in reacting flows in combustion chambers is one of the most important stages in the calculation of heat transfer processes in real combustion chambers.

At the calculations connected with radiant heat exchange, the characteristic values are the radiation energy \( E \) and the spectral intensity \( I_\nu \). To describe the change in the magnitude of the spectral intensity in time, an infinitesimal volume is allocated in the investigated space, with an area \( dA \) and a length \( ds \), in which emission, absorption and scattering of electromagnetic radiation quanta occur.

Thus, the change in the radiation intensity \( I_\nu \) along the infinitesimal volume can be written in the form of the energy balance equation (8):

\[
\frac{1}{c} \frac{\partial I_\nu}{\partial t} + \frac{\partial I_\nu}{\partial x_j} = -\left( K_{\text{abs},\nu} + K_{\text{sc},\nu} \right) I_\nu + K_{\text{abs},\nu} I_\nu + \frac{K_{\text{sc},\nu}}{4\pi} \int \left( P(\Omega, \rightarrow \Omega) \cdot I_\nu(\Omega) \right) d\Omega
\]  

(8)

In connection with the fact that the change in the radiation intensity in time is much less than the speed of light, the first term in the equation of the balance of radiant energy can be neglected. Due to the fact that the system is in thermodynamic equilibrium and the temperature of the radiant energy of the bodies radiated and absorbed is the same, then we can assume that the absorption and radiation coefficients are equal. In addition, in the paper all the bodies participating in heat transfer by radiation are represented as gray radiators.

Thus, the expression (8) can be written as [15,22]:

\[
\frac{\partial I_\nu}{\partial x_j} = -K_{\text{abs}} I_\nu + K_{\text{abs}} \frac{\sigma T^4}{\pi} + \frac{K_{\text{sc}}}{4\pi} \int \left( P(\Omega, \rightarrow \Omega) \cdot I_\nu(\Omega) \right) d\Omega
\]  

(9)

For calculation of heat exchange by radiation in furnace chamber the model of a stream was used, according to which Eq. (9) is integrated over solid angles, for which flows are assumed to be independent of direction.

III. PHYSICAL AND GEOMETRICAL MODEL OF THE PK-39 BOILER

To solve the systems of differential equations describing the processes of heat and mass transfer in the combustion chamber of the boiler PK-39 of Aksu TPP, the control volume method [6, 18-20] was used.

The essence of the method is that the space of the combustion chamber is divided into control volumes and for each point of space surrounded by a certain volume, the
equations of conservation of physical quantity (mass, momentum, energy, etc.) are solved.

Before the numerical experiments using the PREPROZ program [22], files and startup programs were created for two investigated cases, including initial and boundary conditions, the characteristics of the fuel (elemental composition, heat of combustion, fractional composition of Ekibastuz coal), the geometry of the boiler and burner devices [6,13,23]. The main characteristics of the combustion chamber of the boiler PK-39 of Aksu TPP and burnt Ekibastuz coal are presented in table 1.

Fig. 1 provides a general view and a gridding of the PK-39 boiler: for traditional pulverized coal combustion (Fig. 1a), at implement of secondary air nozzles – OFA (Fig. 1b). The major structural characteristics are presented in table 2. In the work, cases with a percentage of the supply air through the nozzles OFA equal to 0 (base case), 10 and 20% of the total amount of secondary and tertiary air supplied to the combustion chamber.

### IV. RESULTS AND DISCUSSION

Results of researches obtained with the FLOREAN software package [25-30] are presented below in the paper. Fig. 2 shows the distribution of the full-velocity vector in different sections of the combustion chamber for the base case (OFA 0%) and with the use of the overfire air technology (OFA 20%). Analysis of the figures shows that with the use of OFA technology, the combustion process in the central part of the combustion chamber is more intense compared to the base case.

Fig. 2. The distribution of the velocity vector in different sections of the combustion chamber a) the central longitudinal section (Y=5.38 m); b) the cross-sectional area of the OFA-nozzles (Z=15.735 m); c) cross-section at the outlet from the combustion chamber of the boiler PK-39 (Z=29.595 m)

Fig. 3. Temperature distribution over the height of the combustion chamber of the boiler PK-39 for different values of air supplied through the nozzles OFA and comparison with experiment [24].

Fig. 4. Distribution of CO$_2$ concentration along the furnace chamber height for different values of air supplied through the nozzles OFA and comparison with experiment [24].

Analysis of Fig. 5 allows us to conclude that an increase in the mass flow of air supplied through OFA injectors leads to a decrease in NO concentration at the outlet from the furnace chamber of PK-39 boiler of Aksu TPP. This is confirmed by the known dependence of NO oxides formed on temperature [31] and analysis of the temperature distribution in the combustion chamber of the boiler PK-39, presented in Fig. 3.

Fig. 5. Distribution of NOx concentration along the furnace chamber height for different values of air supplied through the nozzles OFA

Fig. 6. The effect of the percentage of mass air flow through the OFA injectors on the NO concentration at the outlet from the combustion chamber of the PK-39 boiler of the Aksu TPP

The increase in air supplied through the OFA injectors allows to reduce the concentration of nitric oxide at the outlet from the combustion chamber approximately on 20%. The results of the studies are presented in the form of a diagram in Fig. 6.
V. Conclusion

This paper presents the experiments on the implementation of the overfire air technology on the example of combustion chamber of PK-39 boiler of Aksu TPP. This technology is based on the separation of the oxidant supplied to the combustion chamber in such a way as to reduce the amount of fuel NOx in the burner location by reducing excess air, and reduce the amount of thermal NOx by reducing the temperature of the flame in the region of the location of the OFA-injectors.

Studies show that the implementation of OFA technology on the boiler PK-39 Aksu TPP leads to a change in the distribution of temperature T, the concentrations of carbon CO₂ and nitrogen NOx in the combustion chamber.

Thus, the studies in this paper demonstrate that overfire air technology is one of the most promising ways to reduce emissions of harmful substances (nitrogen oxide NOx and carbon dioxide CO₂) in the atmosphere and can be used in the combustion of high-ash fuels in combustion chambers of coal-fired TPPs.

Nomenclature

- $u_i$ – components of the velocity, m/s;
- $t$ – time, s;
- $\rho$ – density, kg/m³;
- $\tau_{ij}$ – tensor of viscous tension;
- $p$ – pressure, Pa;
- $f_i$ – volume forces, N;
- $h$ – enthalpy;
- $q'^e$ – energy flux density due to molecular heat transfer;
- $S_i$ – a source of energy;
- $c_n$ – mass concentration of the components of the substance;
- $D_n$ – the diffusion coefficient of a component;
- $S_{cn}$ – the source term taking into account the contribution of the chemical reactions in the change in the concentration of components;
- $k$ – turbulent kinetic energy per unit mass;
- $\mu_{eff}$ – effective viscosity;
- $\sigma_o, \sigma_e$ – turbulent Prandtl numbers – empirical constants in turbulence model;
- $P$ – the production of turbulent kinetic energy, which is determined by the following equation;
- $\varepsilon$ – dissipation rate of turbulent kinetic energy per unit mass;
- $\delta_{ij}$ – Kronecker delta;
- $\mu_{turb}$ – turbulent viscosity;
- $c_{1t}, c_{2t}, c_p$ – empirical constants;
- $\nu$ – frequency of radiant energy emitted from the element area;
- $ds$ – length of the infinitesimal element allocated in space;
- $K_{abs}, K_{sca}$ – optical absorption and scattering coefficients;
- $\Omega$ – the solid angle;
- $A_i, B_i$ – the coefficients in the Taylor series expansion – functions of intensity of radiation;
- $\sigma$ – Stefan-Boltzmann constant;
- $b_{ij}$ – the matrix coefficient.
