Abstract: This paper suggested a new family of estimators for the population mean in the simple random sampling using the information of an auxiliary attribute. Theoretically, the mean square error (MSE) equations were obtained and it was shown that all the suggested ratio estimators are more efficient than some known estimators. These results were also supported by two original data sets.

Keywords
Ratio estimator, Simple random sampling, Auxiliary attribute, Mean square error, Efficiency

1. Introduction

When there are positive correlation between study variable \(y_i\) and auxiliary variable \(x_i\) in the simple random sampling method, ratio-type estimators are used to estimate population mean. In the sampling literature, one way to increase the efficiency of an estimator is to use auxiliary attributes. Many authors have suggested estimators based on auxiliary attributes. Zaman [1], Kadilar and Cingi [2], Naik and Gupta [3], Kadilar and Cingi [4], Shabbir and Gupta [5], Singh et al. [6], Abd-Elfattah et al. [7], Koyuncu [8], Malik and Singh [9], Zaman [10] have considered the problem of estimating population mean \(\bar{Y}\) taking into consideration the correlation between the study variable and the auxiliary attribute.

Zaman [1] proposed ratio estimators in order to estimate population mean of study variable \(y\), using information about population proportion possessing certain attributes in simple random sampling:

\[
t_{pr1} = \frac{\bar{y} + b_{p}(p-p)}{p + \beta_1(\varphi)} [P + \beta_1(\varphi)]
\]

\[
t_{pr2} = \frac{\bar{y} + b_{p}(p-p)}{\beta_1(\varphi) + \beta_2(\varphi)} [\beta_1(\varphi)P + \beta_2(\varphi)]
\]

where \(C_p\), \(\beta_1(\varphi)\) and \(\beta_2(\varphi)\) are the population coefficient of variation, the population coefficient of kurtosis of auxiliary attribute and the population coefficient of skewness of auxiliary attribute, respectively and \(b_{p} = \frac{s_{yp}}{s_{p}}\) is the regression coefficient.

Here, \(s_{p}^2\) is the sample variance of auxiliary attribute and \(s_{yp}\) is the sample covariance between the auxiliary attribute and the study variable. Expressions for the MSE’s of the suggested ratio-type estimators is as follows:

\[
MSE(t_{pri}) = \frac{1}{n} \left[ R_1^2 s_{p}^2 + s_{yp}^2 (1 - R_p^2) \right], i = 1, 2, ..., S
\]

\[
R_1 = \frac{\bar{y}}{p + \beta_1(\varphi)}
\]

\[
R_2 = \frac{\bar{y} \beta_1(\varphi)}{p \beta_1(\varphi) + \beta_2(\varphi)}
\]
\begin{align*}
R_3 &= \frac{\bar{y} \beta_2(q)}{p \beta_2(q) + \beta_1(q)} \quad (9) \\
R_4 &= \frac{\bar{y} \beta_3(q)}{p \beta_3(q) + \beta_1(q)} \quad (10) \\
R_5 &= \frac{\bar{y} c_p}{p c_p + \beta_1(q)} \quad (11)
\end{align*}

Zaman [1] deduced that all estimators, given above, were more efficient than the sample mean, the ratio estimator suggested by Naik and Gupta [3], under certain restrictions. Moreover, these results were supported by the results of the original data sets which will also be used in this article.

In the next section, the novel ratio-type estimators are proposed by improving the ratio estimators presented in Zaman [1] by combining them. Then, the MSE expressions of these novel estimators are obtained. In section 4, in addition, comparisons are done among all the proposed estimators numerically. In the last section, conclusions are summarized based on the results of the paper.

2. Suggested Estimators

In this section, new estimators are proposed following the procedure presented in Kadilar and Cinigi [2] combining ratio-type estimators between (1) and (5). The general form of the proposed estimators are as follows;

\[ z_{pri} = \frac{\bar{y} \beta_2(p) + \beta_1(q)}{p+\beta_1(q)} \quad (12) \]

where \( \theta \) is a real constant to be determined such that the MSE of \( z_{pri} \) is minimum. \( k \neq 0 \) and \( l \) are either real number or the functions of known parameters such as \( c_p \beta_1(q) \) and \( \beta_2(q) \), as (1)-(5)

Expressions for the MSE’s of these estimators can be computed using the first-degree approximation in the Taylor series approach as Equation 12. In general, Taylor series method for \( k \) variables can be given as;

\[ h(\bar{x}, \bar{x}_2, \ldots, \bar{x}_k) = \sum_{j=1}^{k} d_j (\bar{x}_j - \bar{x}_j) + R_k(\bar{x}, \alpha) + O_k \]

where

\[ d_j = \frac{\partial h(\bar{x}, \bar{x}_2, \ldots, \bar{x}_k)}{\partial x_j} \quad (14) \]

And

\[ R_k(\bar{x}, \alpha) = \sum_{j=1}^{k} \left[ \sum_{i=1}^{k} \frac{\partial^2 h(\bar{x}_1, \ldots, \bar{x}_k)}{\partial x_i \partial x_j} \right] (\bar{x}_j - \bar{x}_j)(\bar{x}_i - \bar{x}_i) + O_k \quad (15) \]

where \( O_k \) represents the terms in the expansion of the Taylor series of more than the second degree [11].

When we omit the term \( R_k(\bar{x}_k, \alpha) \), we obtain Taylor series method for two variables as follows;

\[ h(p, \bar{y}) - h(P, \bar{y}) \equiv \left[ \frac{\partial h_c(c_d)}{\partial c} \right]_{p, \bar{y}} (p - P) + \left[ \frac{\partial h_c(c_d)}{\partial \bar{y}} \right]_{P, \bar{y}} (\bar{y} - \bar{y}) \quad (16) \]

where, \( h(p, \bar{y}) = z_{pri} \) and \( h(P, \bar{y}) = \bar{y} \). MSE equations of the proposed estimators compute as follows:

\[ x_{pri} - \bar{y} \equiv \frac{\left[ \frac{\partial h_c(c_d)}{\partial c} \right]_{p, \bar{y}} (p - P)}{p} \quad (17) \]

\[ x_{pri} - \bar{y} \equiv \frac{\left[ \frac{\partial h_c(c_d)}{\partial c} \right]_{p, \bar{y}} (p - P)}{p} \quad (18) \]

\[ x_{pri} - \bar{y} \equiv \frac{\left[ \frac{\partial h_c(c_d)}{\partial c} \right]_{p, \bar{y}} (p - P)}{p} \quad (19) \]

If we take the square of each side and take the expected value is passed;

\[ E(x_{pri} - \bar{y})^2 \equiv \left( \frac{\partial (B_p + R_1)}{p + \beta_1(q)} \right)^2 V(p) \quad (20) \]

\[ \gamma_i = \partial (B_p + R_1) + (1 - \partial) (B_p + R_1) \quad (21) \]

\[ R_i = \frac{\gamma_i}{B_p + R_1} \quad (22) \]

\[ MSE(z_{pri}) \equiv \frac{1}{n} \left[ y_i^2 S_2^2 - 2 y_i S_{yp} + S_y^2 \right] \quad i = 1, 2, \ldots, 5 \quad (24) \]

The suggested estimator by combining the estimators presented in (1) and (2) is follows;

\[ z_{pri} = \frac{\bar{y} \beta_2(p) + \beta_1(q)}{p + \beta_1(q)} \quad (25) \]

The MSE of this estimator is found as follows;

\[ MSE(z_{pri}) \equiv \frac{1}{n} \left[ y_i^2 S_2^2 - 2 y_i S_{yp} + S_y^2 \right] \quad (26) \]
where
\[ \gamma_1 = \vartheta (B_\varphi + R_1) + (1 - \vartheta) (B_\varphi + R_2) \]  
(27)

The suggested estimator by combining the estimators presented in (1) and (3) is also as follows;
\[
\begin{align*}
Z_{pr2} &= \frac{\vartheta \frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (P + \beta_1 (\varphi))}{\gamma + b_\varphi (1 - \varphi) (\beta_2 (\varphi) P + \beta_1 (\varphi))} \\
&+ (1 - \vartheta) \frac{\frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (\beta_2 (\varphi) P + \beta_1 (\varphi))}{C_p P + \beta_1 (\varphi)} \\
\end{align*}
\]
(28)

The mean square error of the estimator is the same as (26) but R2 in (27) is replaced with R3.

Moreover, the following estimator is suggested by combining ratio estimator given in (1) and (4),
\[
\begin{align*}
Z_{pr3} &= \frac{\vartheta \frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (P + \beta_1 (\varphi))}{\gamma + b_\varphi (1 - \varphi) (\beta_2 (\varphi) P + \beta_1 (\varphi))} \\
&+ (1 - \vartheta) \frac{\frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (\beta_2 (\varphi) P + \beta_1 (\varphi))}{C_p P + \beta_1 (\varphi)} \\
\end{align*}
\]
(29)

The mean square error of this estimator is again the same as (26) but R2 in (27) is replaced with R4.

Finally, it is suggested the estimator by combining ratio estimators given in (1) and (5) is follows,
\[
\begin{align*}
Z_{pr4} &= \frac{\vartheta \frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (P + \beta_1 (\varphi))}{\gamma + b_\varphi (1 - \varphi) (\beta_2 (\varphi) P + \beta_1 (\varphi))} \\
&+ (1 - \vartheta) \frac{\frac{\gamma + b_\varphi (1 - \varphi)}{\beta_1 (\varphi)} (\beta_2 (\varphi) P + \beta_1 (\varphi))}{C_p P + \beta_1 (\varphi)} \\
\end{align*}
\]
(30)

The mean square error of the estimator is also the same as (26) but R2 in (27) is replaced with R5.

The optimum value of \( \vartheta \) to minimize (26) can easily be computed as follows;
\[
\frac{\partial \text{MSE}(Z_{pr1})}{\partial \vartheta} = \frac{1 - \frac{f}{n}}{2} \left( \gamma_1 S_y^2 - 2 \gamma_1 S_{yp} \right) = 0
\]
(31)
\[
\delta_1 (\delta, S_y^2 - S_{yp}) = 0
\]
(32)
\[
(R_1 - R_{i1}) \left[ \delta (R_1 - R_{i1}) + B_\varphi + R_{i1} S_p^2 - S_{yp} \right] = 0
\]
(33)
\[
\delta (R_1 - R_{i1}) + B_\varphi + R_{i1} = B_\varphi
\]
(34)
\[
\vartheta = \frac{R_{i1}}{R_1 - R_{i1}}; \quad i = 2, ..., 5
\]
(35)

When it is used \( \vartheta^* \) instead of \( \vartheta \) in (16), we get \( \gamma_1 = B_\varphi \). As \( \gamma_1 \) is independent of \( R_2 \), all suggested ratio estimators have the same minimum MSE as follows
\[
\text{MSE}_{\min}(Z_{pri}) = \frac{1 - \frac{f}{n}}{2} (S_y^2 - 2 B_\varphi S_{yp} + B_\varphi^2 S_p^2)
\]
(36)

It can also write this expression by
\[
\text{MSE}_{\min}(Z_{pri}) = \frac{1 - \frac{f}{n}}{2} S_y^2 (1 - \rho_{pb}^2)
\]
(37)

3. Efficiency Comparisons

In this section, it is compared the mean square error of suggested estimators, given in (36), with the MSE of ratio estimators given in Zaman [1], presented in (6). As it is obtained the following condition by these comparison:
\[
\text{MSE}_{\min}(Z_{pri}) < \text{MSE}(t_{pri})
\]
(38)
\[
\frac{1 - f}{n} S_y^2 (1 - \rho_{pb}^2) < \frac{1 - f}{n} \left[ R_1^2 S_p^2 + S_y^2 (1 - \rho_{pb}^2) \right]
\]
(39)
\[
R_1^2 S_p^2 > 0
\]
(40)

We can conclude that all suggested estimators are more efficient than all ratio-type estimators presented in Zaman [1] in all restrictions, because the restriction given in (40) is always satisfied.

Secondly, it is compared the mean square error of the suggested estimators presented in (37) with the variance of sample mean, so we have the following restriction:
\[
\text{MSE}_{\min}(Z_{pri}) < \text{Var}(\bar{y})
\]
(41)
\[
\frac{1 - f}{n} S_y^2 (1 - \rho_{pb}^2) < \frac{1 - f}{n} S_y^2
\]
(42)
\[
\rho_{pb}^2 > 0
\]
(43)

Because this restriction is always satisfied, suggested estimators are more efficient than the sample mean.

Finally, it is compared the mean square error of the suggested estimators presented in (37) with the the ratio estimator suggested by Naik-Gupta [3], so we have the following restriction:
\[
\text{MSE}_{\min}(Z_{pri}) < \text{MSE}(t_{NG})
\]
(44)
\[
\frac{1 - f}{n} S_y^2 (1 - \rho_{pb}^2) < \frac{1 - f}{n} \left( S_y^2 - 2 R_\varphi S_{py} + R_\varphi^2 S_p^2 \right)
\]
(45)
\[
\rho_{pb}^2 > \frac{2R_\varphi S_{py} - R_\varphi S_p^2}{S_y^2}
\]
(46)

When the restriction (46) is satisfied, the suggested estimators are more efficient than the ratio estimator suggested by Naik-Gupta [3].

4. Empirical study

We have used the same data sets as in Zaman [1] to compare the efficiencies of the suggested estimators with the ratio-type estimators numerically.

The statistics about the populations I and II are presented in Tables 1 and 2 respectively. Note that the sample sizes as \( n = 20 \), \( n = 30 \) [12].
Population I (Source: see Sukhatme (1957), p. 279) [13]

\[ y = \text{Number of villages in the circles} \]  \hspace{1cm} (47)

\[ 
\phi_i = \begin{cases} 
1, & \text{if } y > 5 \\
0, & \text{otherwise} 
\end{cases} \hspace{1cm} (48)

When examining the conditions determined in Section 3 for these data sets, they are satisfied for the proposed estimators as follows;

For population I;

\[ R_i^2 S_p^2 > 0, \ i = 1, 2, ..., 5 \] \rightarrow Conditions (40) is always satisfied. \( \rho_{pb}^2 > 0 \) \rightarrow Conditions (43) is always satisfied. \( \rho_{pb}^2 = 0.587 \geq \frac{2\sigma_{xy}^2 - R_i^2 S_p^2}{S_p^2} = -13.03 \rightarrow \)

Conditions (46) is satisfied.

For population II;

\[ R_i^2 S_p^2 > 0, \ i = 1, 2, ..., 5 \] \rightarrow Conditions (40) is always satisfied. \( \rho_{pb}^2 > 0 \) \rightarrow Conditions (43) is always satisfied. \( \rho_{pb}^2 = 0.635 \geq \frac{2\sigma_{xy}^2 - R_i^2 S_p^2}{S_p^2} = -4.97 \rightarrow \)

Conditions (46) is satisfied.

In Table 3, values of mean square error, which are computed using equations given in Sections 1 and 2, are presented. When it is examined Table 3, it is observed that the suggested estimators have the smallest mean square error value among all ratio-type estimators presented Section 1. This is an expected results, as mentioned in Section 3 since the conditions presented in (40) and (43) are always satisfied.

Table 3. MSE values of the Ratio Estimators

<table>
<thead>
<tr>
<th>Estimator</th>
<th>MSE</th>
</tr>
</thead>
</table>

From the result of these numerical illustrations, it is deduced that all the suggested estimators are more efficient than all ratio-type estimators for these data sets.

5. Conclusions

New ratio-type estimators were produced by combining the ratio estimators considered in Zaman [1] the minimum MSE equations were obtained for the suggested estimators. Theoretically, it was shown that all the suggested estimators are always more efficient than the ratio-type estimators. These theoretical results are also supported numerically using the same original data sets as in Zaman [1].
