Inguinal bladder hernia, a rare cause of inguinal herniation: Report of two cases

Nadir bir inguinal herniasyon nedeni olan inguinal mesane fıtığı: İki olgu sunumu

Abstract

Hernia surgery is the most frequent in visceral surgery. The bladder is rarely involved in groin hernia. This is when a diverticulum or a part of the bladder wall is incarcerated within the hernia. This affection is often asymptomatic. The diagnosis is made per or post-operatively following complications. We report 2 cases of inguinal hernia involving the bladder in which the first case was diagnosed preoperatively whereas the second was diagnosed intraoperatively.

Introduction

Bernard Levine was the first to describe bladder hernia in 1951 as a scrotal cystocele [1]. Bladder inguinal hernia is a rare pathology found in about 1-4% of inguinal hernias [2]. The diagnosis is usually done intraoperatively or sometimes postoperatively following the onset of complications. Surgery is the required treatment option; it involves reintegrating the herniated part of the bladder and performing a herniorrhaphy. Patients often have associated urological symptoms. Inguinal bladder hernia constantly remains unknown to the surgeon before diagnosis is made during surgery. We report two cases of inguinal hernia with bladder involvement in which diagnosis was obtained preoperatively for the first and intraoperatively for the second.
Case presentation

Case 1
A 50-year-old patient without any significant medical history who complained of dysuria, pollakiuria, urinary urgency associated with a burning sensation during micturition. The patient explained that the symptomatology had evolved during 6 months and had aggravated by the appearance of a right inguinal painless, reducible swelling which was impulsive to cough. It is important to note that the inguinal swelling increased in volume during pre-micturition and reduces after micturition "Mery's Sign”. Digital rectal examination found a normal palpable prostate.

An abdominopelvic computed tomography (CT) scan was performed which revealed a right inguinal cystocele (Figure 1). The patient was scheduled for surgery. The Surgical exploration revealed a direct inguinal hernia associated with involved the bladder (Figure 2). The surgical treatment consisted of a repositioning of the bladder in an anatomical position and Lichtenstein tension free hernia repair. The postoperative course was uneventful.

Case 2
A 80-year-old patient, who was being treated in the department of urology for benign prostatic hypertrophy, was admitted to the emergency department for a painful swelling on the left groin. Clinical examination found an inguinal a painful, irreducible swelling with a negative cough impulse. The diagnosis of strangulated left inguinal hernia was retained. No radiological examination was performed. The patient was admitted to the operating room for an emergency surgery.

The surgical exploration revealed a thick hernia sac. Bladder involvement was ascertained as the after the hernia sac was incised making it possible to perceive the balloon of the urine catheter (Figure 3). The surgical treatment consisted of the suture of the injured bladder wall. The bladder was repositioned it’s an anatomical position. Bassini technique was used to repair the hernia. The postoperative course was uneventful.

Discussion
Inguinal bladder hernia represents 1 to 4% of all inguinal hernias and mainly affects male patients aged between 50 and 80 years [1,3,4]. The existence of obstructive urinary tract disorders is a risk factor for the disease [5]. Although more this disorder may be frequently due to a prostatic pathology frequent in males. Bladder hernia can also occur in females [6].

Inguinal hernia of the Bladder can touch a bladder wall, a diverticulum or even the entire bladder. They are responsible for symptoms ranging from simple irritative symptoms to acute obstructive renal failure [7]. A two-step urination, facilitated by applying pressure on the hernia and the disappearance of the hernia after the voiding, constitutes a very revealing but inconstant clinical sign: Mery's Sign [8]. However, this pathology often remains asymptomatic. As a result, the diagnosis is usually made intraoperatively.

The diagnosis is often made preoperatively. Radiographic imaging can help obtain the diagnosis in order to reduce the risk of bladder injury during hernia repair when urinary symptoms are present. Indeed, less than 7% of bladder hernias are diagnosed before surgery, while in 16% of cases it is diagnosed postoperatively in the presence of parietal suppuration or vesico-cutaneous fistula [9].

Ultrasound or abdominal CT scan allows diagnosis of bladder hernia [10], CT scan can identify the contents of the hernia (intestine / omentum / bladder) as well as the associated complications. Retrograde urethrocystography performed in search of stenosis of the urethra may objectify an inguinal bladder hernia. They appear as a rounded, unilateral, regular image of addition, communicating widely with the bladder [11].

The treatment consists of a hernia surgery with reintegration of the bladder in an anatomical position. In case of voluminous hernia, bladder diverticulum, or vesical necrosis, the herniated part can be resected. In case of preoperative diagnosis the treatment of a bladder hernia does not differ from that of other hernias and consists of a bladder repression associated with...
a hernia repair. Resection of the bladder is required due to the risk of reduction of bladder capacity and ureteral injury [12].

BPH is a herniogenic factor. The prevalence of inguinal hernia is 15% to 25% in patients admitted for prostate adenoma [13]. In view of the relation between hernia and BPH, it is recommended to treat a BPH with alpha-blockers in the initial therapy. In case of satisfactory improvement of micturition, herniorrhaphy should be performed [14].

In Conclusion: Inguinal bladder hernia is a rare entity and occurs most often in a patient over 50 years of age with a history of urinary incontinence. The symptomatology is nonspecific; the diagnosis is suspected in a patient with an associated urinary disorder (Mery's Sign) and confirmed preoperatively or by computed tomography scan.
