Optimality Conditions of Interval-Valued Optimization Problems by Using Subdifferentials

Emrah KARAMAN

Karabük University, Demir Çelik Campus, Faculty of Science, Department of Mathematics, Karabük, Turkey

Abstract

In this study, interval-valued optimization problems (shortly, interval optimization) are considered. In order to obtain optimality conditions of interval optimization, subdifferential and weak subdifferential are defined. After some properties including an existence condition of the subdifferentials are studied, optimality conditions including the necessary and sufficient conditions for interval optimization are obtained.

Keywords

Optimization, Subdifferential, Optimality condition, Interval optimization

1. INTRODUCTION

Everybody can meet an optimization problem in life. The goal of the optimization problems is to find the best or worst of the options. When the coefficients of an optimization problems are real numbers, a scalar optimization problem crops out. However, there are uncertain situations as unexpected weather conditions or traffic. Then, these situations can be expressed by closed intervals. In this case, interval-valued optimization problems, which are also called uncertain optimization in some books or papers, arise.

Recently, interval optimization has been gathering attention because these optimization problems have applications in engineering, mathematics, control circuitry design, economics, signal processing, global optimization, beam physics, orbits, constraint satisfaction, computer graphics, asteroid, robotics, behavioral ecology, etc. Also, these problems are generalization of scalar optimization problems and they are a special case of set optimization problems. More details about the interval optimization and its applications can be found in the following references.

used derivative to obtain solution for interval optimization. But, there is no study to obtain solution of interval optimization by using subdifferential.

There is no natural order relation in order to compare two intervals. Then, some order relations are used to solve the interval optimization problem or compare two intervals. Researchers as Moore [17] and Ishibuchi and Tanaka [18] defined order relations. Since defined order relations are partial order relations, optimal element definitions used for partial order relation are used. Naturally, an efficient element of a family or solution of interval optimization can change when order relation changes.

One of the aim of this study is to obtain some optimality conditions for interval optimization. Subdifferentials are used to achieve this aim. Two subdifferentials are defined and optimality conditions are obtained by using them. In this study, we use the order relation which is given by Moore in [17].

2. MATERIALS AND METHODS

In this part, we recall some fundamental definitions which are used in the next section. Throughout this study, let the class of all bounded and closed intervals (or ranges) in $\mathbb{R}$ be denoted by $\mathbb{I}_C$. An interval number in $\mathbb{R}$ is described as follows: For $a_L \leq a_U$

$$A = [a_L, a_U] = \{x \in \mathbb{R} : a_L \leq x \leq a_U\} = \{x \in \mathbb{R} : \left|x - \frac{a_L + a_U}{2}\right| \leq \frac{a_U - a_L}{2}\}$$

where $a_L$ and $a_U$ are called lower and upper bounds of $A$, respectively. Every real number $x \in \mathbb{R}$ can be considered as a closed and bounded interval as $[x, x]$. Let $A = [a_L, a_U]$ and $B = [b_L, b_U]$ be intervals in $\mathbb{I}_C$ and $k \in \mathbb{R}$. Then, addition, difference of two intervals and scalar multiplication of an interval with scalar $k$ are defined as:

$$A + B = [a_L, a_U] + [b_L, b_U] = [a_L + b_L, a_U + b_U],$$

$$A - B = [a_L, a_U] - [b_L, b_U] = [a_L - b_U, a_U - b_L]$$

and

$$kA = k[a_L, a_U] = \begin{cases} \{ka_L, ka_U\} & \text{if } k \geq 0 \\ \{ka_L, ka_U\} & \text{if } k < 0 \end{cases}$$

respectively. Also, we have $A - B = A + (-B)$ and $-A = -[a_L, a_U] = [-a_U, -a_L]$ from the difference of two intervals. Moreover, difference of two same intervals may not be zero element.

Let $S$ be a nonempty set. Then, interval-valued function (shortly, interval function) $F:S \to \mathbb{I}_C$ is given by $F(s) = [f_L(s), f_U(s)]$ for all $s \in S$ such that $f_L(s) \leq f_U(s)$. Also, $f_L$ and $f_U$ are called lower and upper bounded functions, respectively.

Throughout the article, $F:S \to \mathbb{I}_C$ is considered as an interval function and $S \subset \mathbb{R}^n \ (n \geq 1)$. An interval optimization is defined by

$$(IVOP) \quad \min(max) F(s), \quad s \in S.$$}

In order to obtain the solution and weak solution of $(IVOP)$, we need an order relation on $\mathbb{I}_C$. So, we use the following order relations: For $A = [a_L, a_U], B = [b_L, b_U] \in \mathbb{I}_C$

$$A \preceq B \iff a_U \leq b_L,$$

$$A < B \iff a_U < b_L.$$
This order relation is defined by Moore [17]. These order relations are compatible with nonnegative scalar multiplication. But they aren’t compatible with addition. For example, although $A \lesssim B$, $A + C \not\lesssim B + C$ for $A = [3,4], B = [5,6], C = [-1,3]$. $\lesssim$ is reflexive, transitive and antisymmetric relation, that is partial order relation. Any two intervals may not be compared according to these order relations because order relation $\lesssim$ is not a total order relation. For example, $A = [3,5]$ and $B = [4,6]$.

Now, we give some basic properties of order relations $\lesssim$ and $\prec$. These properties are used to prove the results in the next section.

**Proposition 1.** Let $A, B, C, D \in \mathbb{I}_C$. Then, the following properties are hold:

(i) $A - B \not\equiv 0 \iff A \not\equiv B \iff -B \not\equiv -A$,

(ii) $A \lesssim B$ and $C \lesssim D \Rightarrow A + C \lesssim B + D$,

(iii) $A \lesssim B \Rightarrow A - B \not\equiv 0 \iff B - A \not\prec 0$,

(iv) $A \not\equiv B \Rightarrow A - B \not\equiv 0$,

(v) $A \prec B \iff A - B \not\equiv 0$,

(vi) $A \not\prec B \iff A - B \not\equiv 0$.

**Proof.** The proof can be easily obtained from definitions of $\lesssim$ and $\prec$.

We will use following definition to obtain efficient elements of (IVOP).

**Definition 1.** Let $F \subseteq \mathbb{I}_C$ and $A \in F$. Then,

(i) $A$ is called a minimal (maximal) interval of $F$ if there isn’t any $B \in F$ such that $B \lesssim A$ ($A \lesssim B$) and $A \neq B$,

(ii) $A$ is called a weak minimal (weak maximal) interval of $F$ if there isn’t any $B \in F$ such that $B \prec A$ ($A \prec B$) and $A \neq B$.

If $F(s_0)$ is a minimal (maximal) interval of $F(S) := \{ F(s) : s \in S \}$, then we say that $s_0$ is a solution of (IVOP) or $s_0$ is a minimal (maximal) solution of (IVOP). Similarly, if $F(s_0)$ is a weak minimal (weak maximal) interval of $F(S)$, then we say that $s_0$ is a weak solution of (IVOP) or $s_0$ is called a weak minimal (weak maximal) solution of (IVOP). It is clear that every solution is also a weak solution of the problem.

In the rest of the study, the set of all linear operators, which is defined from $\mathbb{R}^n$ into $\mathbb{R}$, are denoted by $\mathcal{L}(\mathbb{R}^n, \mathbb{R})$.

### 3. RESULTS AND DISCUSSION

In this section, two subdifferentials are defined. After some basic properties of subdifferentials are examined, optimality conditions are obtained for (IVOP).

**Definition 2.** A linear operator $L: \mathbb{R}^n \rightarrow \mathbb{R}$ is called a subgradient of $F$ at $s_0 \in S$ if $F(s) - F(s_0) < L(s - s_0)$ for all $s \in S \setminus \{ s_0 \}$. The set of all subgradients of $F$ at $s_0$ is called subdifferential of $F$ at $s_0$ and denoted by $\partial F(s_0)$.

**Definition 3.** A linear operator $L: \mathbb{R}^n \rightarrow \mathbb{R}$ is called a weak subgradient of $F$ at $s_0 \in S$ if $F(s) - F(s_0) \lesssim L(s - s_0)$ for all $s \in S$. The set of all weak subgradients of $F$ at $s_0$ is called weak subdifferential of $F$ at $s_0$ and denoted by $\partial^w F(s_0)$.

It is clear that $\partial F(s_0) \subseteq \partial^w F(s_0)$. The next example shows that the converse implication is not true in general.

**Example 1.** Let interval function $F: [-1,1] \rightarrow \mathbb{I}_C$ be defined as $F(x) = [x^2, x]$ for all $x \in [-1,1]$. Then, we obtain $\partial F(0) = \emptyset$ and $\partial^w F(0) = \{1\}$. Although $\partial F(0) \subseteq \partial^w F(0)$, we have $\partial^w F(0) \not\subseteq \partial F(0)$. 

Proposition 2. Let \( s_0 \in K \). Then, \( \partial F(s_0) \) and \( \partial^w F(s_0) \) are convex functions.

**Proof.** We prove for \( \partial F(s_0) \) and second part for \( \partial^w F(s_0) \) is obtained similarly. Let \( L_1, L_2 \in \partial F(s_0) \) and \( t \in [0,1] \). Then, we get \( F(s) - F(s_0) < L_1(s - s_0) \) and \( F(s) - F(s_0) < L_2(s - s_0) \) for all \( s \in S \setminus \{s_0\} \). Because \( < \) is compatible with nonnegative scalar multiplication, we have \( tF(s) - tF(s_0) < tL_1(s - s_0) \) and \( (1 - t)F(s) - (1 - t)F(s_0) < (1 - t)L_2(s - s_0) \) for all \( s \in S \setminus \{s_0\} \). Then, we get \( tF(s) - tF(s_0) + (1 - t)F(s) - (1 - t)F(s_0) < tL_2(s - s_0) + (1 - t)L_2(s - s_0) \) from Proposition 1 (ii). This gives \( F(s) - F(s_0) < tL_1(s - s_0) + (1 - t)L_2(s - s_0) = (tL_1 + (1 - t)L_2)(s - s_0) \) for all \( s \in S \setminus \{s_0\} \). Hence, \( tL_1 + (1 - t)L_2 \in \partial F(s_0) \) and \( \partial F(s_0) \) is convex function.

Proposition 3. Let \( t \in \mathbb{R}_+ \). Then, \( \partial(tF)(s_0) = t \partial F(s_0) \) for all \( x_0 \in S \).

**Proof.** Since the order relation \( \preceq \) is compatible with nonnegative scalar multiplication, we get

\[
t \partial F(s_0) = t\{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}) : F(s) - F(s_0) < L(s - s_0), s \in S \setminus \{s_0\}\} = \{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}) : F(s) - F(s_0) < \frac{2}{t}(s - s_0), s \in S \setminus \{s_0\}\} = \{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}) : tF(s) - tF(s_0) < L(s - s_0), s \in S \setminus \{s_0\}\} = \partial(tF)(s_0).
\]

Proposition 4. Let \( s_0 \in S \). Then, the set \( \partial F(s_0) \) is closed for all \( s_0 \in S \).

**Proof.** If \( \partial F(s_0) = \emptyset \), then proof is completed. Assume that \( \partial F(s_0) \neq \emptyset \) and \( L \in \text{cl}(\partial F(s_0)) \). We show \( L \in \partial F(s_0) \).

Suppose to the contrary that \( L \notin \partial F(s_0) \). Then, there exists a \( s_0 \in S \) such that \( F(s) - F(s_0) \preceq L(s - s_0) \).

Since \( L \in \text{cl}(\partial F(s_0)) \) there exists a sequence \( L_n \in \partial F(s_0) \) such that \( L_n \to L \). Because \( L_n \in \partial F(s_0) \) for all \( n \in \mathbb{N} \), we have

\[
F(s) - F(s_0) < L_n(s - s_0) \quad \text{for all} \quad x \in S \setminus \{s_0\}.
\]

As interval \( L_n(s - s_0) - F(s) + F(s_0) \) is closed and bounded set, we get \( F(s) - F(s_0) \preceq L(s - s_0) \) for \( n \to \infty \). Hence, \( L \in \partial F(s_0) \). This is a contradiction. Therefore, \( \partial F(s_0) \) is closed.

Proposition 5. Let \( F, G : X \to \mathbb{I}_c \) be interval functions and \( s_0 \in S \). Then, \( \partial F(s_0) + \partial G(s_0) \subset \partial(F + G)(s_0) \).

**Proof.** Let \( L_1 \in \partial F(s_0) \) and \( L_2 \in \partial G(s_0) \). Then, we have \( F(s) - F(s_0) < L_1(s - s_0) \) and \( G(s) - G(s_0) < L_2(s - s_0) \) for all \( s \in S \setminus \{s_0\} \). From Proposition 1 (ii), we have \( F(s) - F(s_0) + G(s) - G(s_0) < L_1(s - s_0) + L_2(s - s_0) \), i.e. \( (F + G)(s) - (F + G)(s_0) < (L_1 + L_2)(s - s_0) \). Then, \( L_1 + L_2 \in \partial (F + G)(s_0) \), i.e. \( \partial F(s_0) + \partial G(s_0) \subset \partial (F + G)(s_0) \).

Now, we give an existence condition of subdifferential of an interval function.

Proposition 6. Let \( s_0 \in S \). If there exist a constant \( C \) such that

\[
C|s - s_0| \preceq F(s) - F(s_0)
\]

for all \( s \in S \setminus \{s_0\} \), then \( \partial F(s_0) \neq \emptyset \).

**Proof.** Assume that there is a constant \( C \) such that \( C|s - s_0| \preceq F(s) - F(s_0) \) for all \( s \in S \setminus \{s_0\} \). Then, we have \( F(s) - F(s_0) < C|s - s_0| \) for all \( s \in S \setminus \{s_0\} \). Hence, we yield \( C \in \partial F(s_0) \neq \emptyset \) from definition of subdifferential.
In the rest of the study, we will give the optimality conditions for (IVOP).

**Theorem 1.** Let \( s_0 \in S \). \( s_0 \) is a minimal solution of (IVOP) if and only if \( 0 \notin \partial F(s_0) \).

**Proof.** Assume that \( s_0 \) is a minimal solution of (IVOP). Then, we have \( F(s) \not< F(s_0) \) for all \( s \in S \setminus \{s_0\} \). By Proposition 1 (iv), we get \( F(s) \not< F(s_0) \forall s \in S \setminus \{s_0\} \). So, \( 0 \notin \partial F(s_0) \).

The other direction can be obtained similarly.

**Theorem 2.** Let \( s_0 \in S \). If \( 0 \notin \partial F(s_0) \), then \( s_0 \) is a maximal solution of (IVOP).

**Proof.** Let \( 0 \notin \partial F(s_0) \). Then \( F(s) \not< F(s_0) \forall s \in S \setminus \{s_0\} \). From Proposition 1 (v), we get \( F(s) \not< F(s_0) \forall s \in S \setminus \{s_0\} \). Hence, \( F(s) \leq F(s_0) \forall s \in S \setminus \{s_0\} \) and \( s_0 \) is a maximal solution of (IVOP).

**Corollary 1.** Let \( s_0 \in S \). If \( 0 \notin \partial F(s_0) \), then \( s_0 \) is a weak maximal solution of (IVOP).

**Theorem 3.** Let \( s_0 \in S \). If \( 0 \notin \partial^w F(s_0) \), then \( s_0 \) is a maximal solution of (IVOP).

**Proof.** The proof can be obtained similar to Theorem 2 by using Proposition 1 (iii).

**Example 2.** Let interval function \( F: [-1,1] \to I_c \) be defined as \( F(x) = [x^2, |x|] \) for all \( x \in [-1,1] \). Consider the following interval optimization

\[
(IVOP) \left\{ \begin{array}{l}
\min (\max) \ F(x) \\
x \in [-1,1]
\end{array} \right.
\]

Let’s calculate subdifferential and weak subdifferential of \( F \) at 0 and 1.

\[
\partial F(0) = \{ L: \mathbb{R} \to \mathbb{R} : F(x) - F(0) < L(x), x \in [-1,1] \setminus \{0\} \}
\]

\[
= \{ t \in \mathbb{R} : F(x) < tx, x \in [-1,1] \setminus \{0\} \}
\]

\[
= \{ t \in \mathbb{R} : [x^2, |x|] < tx, x \in [-1,1] \setminus \{0\} \}
\]

\[
= \{ t \in \mathbb{R} : |x| < tx, x \in [-1,1] \setminus \{0\} \}
\]

\[
= \emptyset.
\]

Since \( 0 \notin \partial F(0) \), 0 is a minimal solution of (IVOP) from Theorem 1.

\[
\partial^w F(0) = \{ L: \mathbb{R} \to \mathbb{R} : F(x) - F(0) \leq L(x), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : F(x) \leq tx, x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : [x^2, |x|] \leq tx, x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : |x| \leq tx, x \in [-1,1] \}
\]

\[
= \emptyset.
\]

\[
\partial F(1) = \{ L: \mathbb{R} \to \mathbb{R} : F(x) - F(1) < L(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : F(x) - F(1) < t(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : [x^2, |x|] - [1,1] < t(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : |x|^2 - 1, |x| - 1 < t(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : |x| - 1 < t(x - 1), x \in [-1,1] \}
\]

\[
= (-\infty, 1).
\]

Since \( 0 \notin \partial F(1) \), 1 is a maximal solution of (IVOP) from Theorem 2.

\[
\partial^w F(1) = \{ L: \mathbb{R} \to \mathbb{R} : F(x) - F(1) \leq L(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : F(x) - F(1) \leq t(x - 1), x \in [-1,1] \}
\]

\[
= \{ t \in \mathbb{R} : [x^2, |x|] - [1,1] \leq t(x - 1), x \in [-1,1] \}
\]
\[
\{ t \in \mathbb{R} : |x| - 1 \leq t(x - 1), x \in [-1,1] \} = (-\infty, 0].
\]

1 is a weak maximal solution of (IVOP) from Theorem 3 since \(0 \in \partial^w F(1)\).

### 4. CONCLUSION

In this paper, two subdifferentials are considered for interval optimization. Some basic properties including an existence condition are obtained. Also, optimality conditions are derived for corresponding problem. Results are explained by using examples. This method can be applied to other order relations on interval optimization. Some new methods as used in vector or set optimization can be improved. Moreover, this method can also be applied to the optimal control problems in [19,20].
