ABSTRACT

Objective: Cancer has been one of the most critical health problems during the past decades which requires serious consideration, especially in developing countries.

Methods: 80 parents of children with different types of cancers were studied via both questionnaire and person-to-person interviews after declaring their informed consent.

Results: The highest delay in patients' initial referral was due to the following factors: lack of attention or ignoring the first symptoms, delay in referring to the physician, low economic status and even lack of family support for the patient. In addition, visiting several doctors after the initial diagnosis, uncertainty about the first proposed method, and the high cost of treatment can be mentioned as the main causes of delays in the start of treatment.

Conclusion: Education plays an important role in identifying the signs of cancer. In addition, proper relationship and cooperation between the health system and physicians as well as provision of adequate information to patients could lead to the long-term cooperation of these patients in continuing their treatment.

Keywords: Cancer, delay in referral, children, delay in diagnosis, delay in treatment

ÖZET

Amaç: Kanser, son yıllarda, özellikle gelişmekte olan ülkelerde, ciddi dikkat gerektiren en kritik sağlık sorunlarından biri olmuştur.

Yöntem: Farklı kanser türlerine sahip çocukların 80 ebeveyni aydınlatılmış onamları alındıktan sonra hem anket hem de bire bir görüşme yoluyla incelenmiştir.

Bulgular: Hastaların ilk sevindeki gecikmeler, aşağıdaki faktörlerden kaynaklanmaktadır: dikkat eksikliği veya ilk semptomları görmezden gelme, doktora başvurmada gecikme, düşük ekonomik durum ve hatta hasta için aile desteği eksikliği. Ek olarak, ilk tanıdan sonra farklı doktorlara başvurmak, önerilen ilk yöntem hakkında belirsizlik ve yüksek tedavi maliyeti, tedavinin başlangıcındaki gecikmelerin ana nedenleri olarak gösterilebilir.

Sonuç: Eğitim, kanser belirtilerini anlamada önemli bir rol oynamaktadır. Buna ek olarak, sağlık sistemi ve doktorlar arasında ilişki ve işbirliği ile hastalara yeterli bilgi sağlanması, bu hastaların tedavilerini sürdürmede önemli faktörler olarak görünmektedir.

Anahtar Kelimeler: Kanser, sekte gecikme, çocuk, tanıda gecikme, tedavide gecikme

INTRODUCTION

Since the diagnosis and treatment of this disease in its early stages can reduce the related mortality rates and complications, and tangibly reduce the costs, this study attempts to investigate the factors affecting the patients' initial delay in referring to physicians and then proposes some solutions to tackle this problem and reduce its resultant impact.

Cancer can be defined as the "uncontrollable growth of cells" and it is recognized as a major problem in human societies. It causes the highest mortality rate after heart disease (1). It was Hippocrates (460-370 BC), the Greek physician who used the term "carsino" for the first time to refer to this disease. Later, Celsus (50-28 BC) changed it to "cancer", which means "Scorpion" in the Latin and since then the term cancer has been used to date (2).

Initially, cancer was identified as a problem for the health systems of developed countries; however, in the last decades; 1975 to 2012, its rate has been also increasing in developing countries.

Cancer prevalence rates have increased in all age ranges by 0.6% per year. In contrast, death rates have dropped constantly, from 6.5 in 1970 to 2.4 in 2012, per 100,000 population (1). For example, the percentage of patients with breast cancer increased from 75% in 1977 to 90% in 2009 (3).

The high rates of mortality, economic and psychological consequences as well as the disabilities created by cancer impose a huge cost on the health system of every society. This has motivated the conducting of a plethora of studies for the rapid diagnosis of cancer in its early stages for effective treatment (4, 5). With advances in screening, the diagnosis of cancers in their early stages has been made possible. Therefore, many patients can enjoy a good quality of life today because this disease can be diagnosed and treated in early stages (6).

The delay in diagnosis mainly hinges upon two different components:

1. Inattention to the illness symptoms and the patient's delay in referring to a physician (the factors related to the patient).
2. The physician's delay in the initial definitive diagnosis of the disease, which includes the inattention of some physicians to the initial and non-specific symptoms related to cancer, and it is sometimes due to the deceptive and inertial nature of some types of cancers in the early stages (the factors related to the health care system) (7, 8). Delay in the diagnosis of cancer leads to an unrealistic incidence in the rate of cancer.

We know that strategic health plans are based on this information and will be influenced by them. These causes lead to the delay in the initiation of early effective treatment, the increased relapse of the disease, no response to treatment and long-term increase of mortality. The present study tried to distinguish the causes of delay in initial referral, diagnosis and onset of treatment. In this way, we can identify the local factors and take a step forward regarding the achievement of the goals set by the World Health Organization in 2014, which emphasizes the early diagnosis with the start of education and training in schools and the implementation of an early perfect treatment plan (8). Particularly, this issue bears high importance in Iran which is currently dealing with a rise in cancer incidents.

METHODS

In the present study, the participants were selected within one year, from 2015 to 2016, through person-to-person interviews with parents of the patients in the children age group. A total of 93 patients were examined consecutively. The children were divided into two groups, i.e. patients above 7 years of age and 7 years old and below. From all patients, 58 were male and 22 were female with a mean age of 5.93 ± 3.25 years old. Graphical abstract is shown in (Figure 1).

The criterion for the inclusion of participants into the study was cancer development for children who had referred to or had been asked to refer to the Children's Hospital of Tabriz for the first time for the diagnosis of cancer or the beginning of treatment.

The patients who were not willing to be interviewed or the ones who had gone through some part of the diagnosis and treatment process in another country were eliminated from participation in this study. The data were collected through questionnaires, which were completed through interviews by the researchers. Those parents who did not provide the researchers with accurate information or opted out of the interview were also excluded from the study.

In this study, each of the delayed referrals, delayed diagnoses, and delayed treatments were identified via the following definitions. Delay in Referring: a delay of more than 30 days from the emergence of symptoms up to the visit to the physician. Delay in diagnosis: a delay of more than 30 days from the first visit to the physician to diagnosis. Delay in treatment: a delay of more than 14 days from diagnosis to treatment.

Statistical analysis

Normality of data was calculated by Kolmogorov-Smirnov test and expressed by mean and standard deviation in tables. Non-normal variables were implied as median (max & min). The causes of delays difference between 2 groups; with delay and without delay were assessed by

independent sample T-test. P-values less than 0.05 were considered statistically significant. All statistical analyses were done using the Statistical package for the Social Sciences (SPSS), version 16.0 (SPSS Inc, Chicago, IL, USA).

Ethical considerations

The theme of the study was described to all the patients' parents or patients in simple language and the questionnaires with written informed consent were completed with them. The participants were assured that their information would be treated as confidential, would be protected at all research stages, and dissemination of the results would be conducted in an anonymous manner.

RESULTS

From among 93 patients under study, 13 patients were excluded from the study due to their non-compliance with the inclusion criteria and, thereby, a total of 80 patients were finally evaluated. Table 1 shows the information about the number of patients in each delay group.

Causes of delay in the initial referral

In total, a delay of more than one month from the first referral was observed in 5% of the patients. In this study, the relationship of this delay with age, gender, location of residence, occupation, and education of parents was assessed and the following results were obtained:

The relationship between patients' gender and delay in the initial referral

There was no significant correlation ($p > 0.05$) in different groups. Table 2 demonstrates the correlation between gender by each delay.

The relationship between parents' occupation and delay in the initial referral

In this group, similarly, no significant relationship was found; thus, it can be concluded that there was no significant difference between different occupation groups ($p > 0.05$). Table 3 represents the relevance of parent's occupation and each delay.

The relationship between education level of parents and delay in the initial referral

Parents with elementary education referred to the physician with significantly further delays ($p = 0.037$) in comparison with other educational groups. On the contrary, those with secondary and higher education had the lowest delay. Table 4 shows the relation of parents' education and types of delay groups.

The relationship between children's age and delay in the initial referral

The patients were divided into two age groups, i.e. patients above 7 years of age, and patients below 7 years of age (based on school age of onset), however there was no significant difference in any of the groups. Table 5 demonstrates the relationship between age range of children and each delay.

The relationship between residence location and delay in the initial referral

Regarding the residence location of patients, there was no significant difference between urban and rural residents in referring to the physician, diagnosis, and treatment of cancer. Table 6 displays the relation between distance of residence and variety of delays.

Table 1. Number of patients in each of delay groups

Type of delay	Number of patients	≤ 30 days	> 30 days
		Delayed referral	71
Delayed diagnosis	80	≤ 14 days	> 14 days
		60	20
Delayed treatment	80	71	9

Table 2. Correlation between gender and delay groups

Type of delay	Gender	≤ 30 days	> 30 days
		Delayed referral	Male
Female	20		2
Delayed diagnosis	Male	42	16
	Female	18	4
Delayed treatment	Male	53	5
	Female	18	4

Businessman	17	-	
Unemployed	2	-	

Effective factors in delay in the first visit to the physician

About 5% of the patients had a delay of more than one month before the first visit to the physician.

Causes of delayed diagnosis

A large number of factors are at play in this regard. Here, the patients' demographic characteristics were evaluated where delayed diagnosis was not significantly correlated with patients' age and gender nor parents' occupation.

Causes of delayed onset of treatment

Generally, 3.7% of the children had a delay of more than a month regarding the beginning of treatment.

In this study, the reasons that led to delay in the beginning of treatment include:

Visiting several physicians after the final diagnosis

From among 18 patients who had a delay of more than 16 days in the beginning of treatment, 77.7% of them had referred to two or more physicians after the final diagnosis; therefore, these patients had significant delays in regard to the beginning of treatment.

Use of witchcraft, bets and casting of spells as a method of treatment

The parents of 88.8% of the children had used this method for recovery, but only 7.8% of the parents mentioned the use of witchcraft as the reason for delay in regard to

Table 4. Relation parent's education and kinds of delay groups

Type of delay	Parent's education	≤ 30 days	> 30 days
Delayed referral	Mother		
	Illiterate	32	7
	Diploma	18	1
	Academic	21	1
	Father		
	Illiterate	37	3
	Diploma	15	4
	Academic	19	2
	Delayed diagnosis	Mother	
Illiterate		28	11
Diploma		14	5
Academic		18	4
Father

	Diploma	13	6
	Academic	21	1
	Father		
	Illiterate	37	3
	Diploma	14	5
	Academic	20	1

Table 5. children age range and length of delay

Type of delay	Age	≤ 30 days	> 30 days
Delayed referral	< 7 years	41	5
	7 years ≤	30	4
Delayed diagnosis	< 7 years	32	14
	7 years ≤	28	6
		≤ 14 days	> 14 days
Delayed treatment	< 7 years	40	6
	7 years ≤	31	3

the beginning of treatment. Most of them did not refer to witchcraft as a method for the treatment of cancer; in fact, they mentioned witchcraft as a complementary treatment of cancer. They acknowledged that cancer should

be treated with medical and surgical procedures and this referral continued after the start of treatment, but it did not have any preventive power in the continuation of the treatment.

Table 6. Relation between distance of residence and variety of delays

Type of delay	Distance	≤ 30 days	> 30 days
Delayed referral	Urban	29	2
	Rural	42	7
Delayed diagnosis	Urban	27	4
	Rural	33	16
		≤ 14 days	> 14 days
Delayed treatment	Urban	30	1
	Rural	41	8

Table 7. In comparison with kinds of all delays and factors influencing on delays

	Age	Gender	Mother work	Father work	distance	Mother education	Father education
Delay refer	.917	1.000	1.000	.410	.470	R=-.191 .090	R=+.054 .637
Delay diagnosis	.650	.389	.311	.450	.048	R=-.094 .408	R=+.060 .596
Delay treatment	.337	.250	1.000	.097	.143	R=+.043 .707	R=+.006 .955

p<0.05 is significant, R= Pearson's correlation that can range from -1 to 1

Denial of reality

It was revealed that there is no significant relationship between the normal process of psychological reactions to the acceptance of the disease and delay in the onset of treatment.

Mistrust in the treatment

From among the patients who had a delay in the beginning of the treatment, 33.3% of them referred to this factor as the reason for their delay; thus, a long time was spent on searching for other methods to treat the disease.

It should be mentioned that the parents were asked about the distance of the route, their psychological problems after being informed of the cancer diagnosis, high cost of treatment and the reaction of relatives as the possible reasons for delayed treatment. However, they did not mention any of these factors as the ones that might have led to the delay in their referral or in the beginning of treatment, but they found these factors a major cause of continued treatment.

Decision to discontinue treatment

In response to the question of whether or not the parents decided to discontinue treatment 25% of children stated that they had made such a decision at least once, 68% referred to despair of recovery and treatment-related side effects as the reasons, 23% referred to economic factors,

and 9% referred to other factors, such as family problems and lack of family support as the causes of delay.

A comparison of the kinds of delays and factors influencing delays is illustrated in Table 7.

DISCUSSION

With the increase of human longevity and the change of environmental conditions, the improvement of cancer diagnostic methods has witnessed an increasing trend, especially in developing countries where there is a lower quality of environmental factors, food safety, health, and living conditions. However, advances in diagnostic methods have contributed to the identification of cancer patients and this along with the betterment of treatment methods has brought a higher degree of hope for the treatment and increased quality of life in these patients. Since the quick and timely diagnosis has a very important role in the treatment process of cancer, this study sought to evaluate the amounts of the aforementioned delays from the incidence of the first symptoms and to determine the causes of these three types of delays so that basic strategies would be presented with the aim of reducing patients' delay in referral, diagnosis, and treatment.

In the present study, no relationship was found between children's age and delay in referring to the physician; however, a similar study was carried out in Nigeria in 2015

where the results represented the existence of a negative significant correlation between children's age and the delay in diagnosis. In another study which was conducted in South Africa in 2010 by Dr. Stefan's team, a delay in initial referral was found to hold no significant association with age, gender, and ethnicity (9, 10). Similar results with the current findings were also obtained in terms of gender that may lead to the conclusion that most parents did not discriminate between their children in this regard despite the culture of gender discrimination in most societies.

Few studies have been conducted on the role of parents' education and knowledge, especially on children; however, Dr. Stephen also reported similar results (9). In contrast, various studies have been conducted on the overall role of education in diagnosis and treatment at various age groups and the majority of these studies have lent support to the positive effect of education, training, and knowledge in this area (8, 11).

In relation to the difference between urban and rural areas in terms of the initial referral and onset of treatment, Bain and Campbell conducted a study in 2000 at Oxford University and reported that rural patients are less hopeful about treatment and they start their treatment later under the belief that they are faced with more obstacles in receiving intensive care (12). In the same way, a study was undertaken on 200 women with breast cancer at Tehran University in 2005 and residence in rural areas was referred to as the cause of delay in initial referral (13).

In comparison with the result of the present study which was carried out a decade later and due to the non-significance of distance from treatment centers as one of the causes of delay in referral, it can be argued that the expansion of health centers, establishment of family doctors even in the most remote rural areas, and a referral system have played an effectively positive role in this domain. In fact, these patients mentioned other factors, such as referral to multiple physicians after the final diagnosis, denial of reality, lack of confidence in the treatment method, and high costs of treatment as the reasons for their delays. According to the research findings and considering the culture of our country, spells and casting spells are not regarded as an acceptable treatment method for cancer. In fact, patients stated other applications for making spells and have acknowledged that cancer should be treated with medical and surgical methods. However, they emphasized the positive impact on their spirit and psyche of using spells (14, 15).

In a systematic study which was conducted in 2015, the following four factors were identified as the most important causes of delays in referral and seeking treatment: care-giving barriers, coordination of the health system with patients, the type of communication, the interactions of the care-giving system with patients, and patients' personal values and relationships (16).

CONCLUSION

In the population of the present study, such characteristics as age, gender, occupation, and rural residence did not cause any delay in referring to the physician, but other factors, including the assignment of no importance to the primary symptoms and/or the serious consideration of these symptoms, habitual delay in referring to the physician, low level of economic status, lack of family support for the patient, and family problems were found to be the main reasons for such delays.

SUGGESTIONS

According to the research results, the following suggestions are recommended:

- 1) Necessary training and education should be taken more seriously to familiarize the public, especially school students and university students, with the warning signs of cancer.
- 2) Patients and their families who have undergone mental problems after the diagnosis and try to deny reality should be helped immediately to improve this situation through psychoanalysis and social work services.
- 3) If the physician and the treatment system provide the patients and their relatives with necessary information and assurance regarding diagnostic methods and treatment procedures, patients can spend time on the treatment rather than on visiting several doctors.
- 4) The poor and low-income strata should be financially supported and their insurance situation should be improved.
- 5) Convincing the patients about the side effects of treatment will cause them not to think of stopping the continuity of treatment nor to think of treatment discontinuation immediately after relative recovery.
- 6) Early diagnosis of cancer is important for preventing the rising death rate from cancer. In order to improve this situation, it requires a timely visit to the physician, timely diagnosis of the disease, and the improvement of treatment methods.

Acknowledgment: The authors thank all the patients and their parents who participated in study. Also, many thanks to the Department of Molecular Medicine, Faculty of Advanced Medical Science of Tabriz University for their support.
