(Communicated by Lyudmila N. Romakina)

## ABSTRACT

In 1953, Victor Thébault conjectured a link between the altitudes of a tetrahedron and the radical center of the four spheres with the centers at the vertices of this tetrahedron and the corresponding tetrahedron altitudes as radii. This conjecture was proved in 2015. In this paper, we propose an analogue of Thébault's theorem. We establish a link between the radical center of the four spheres, the insphere, and the Monge point of a tetrahedron.

## 1. Introduction

The famous French problemist Victor Thébault (1882–1960) conjectured the following geometric fact linking the radical center of four spheres with other elements of a tetrahedron. Let  $AA'$ ,  $BB'$ ,  $CC'$ ,  $DD'$  be the altitudes of a tetrahedron  $ABCD$  with feet  $A'$ ,  $B'$ ,  $C'$ , and  $D'$ , respectively. Let  $P$  be the radical center of the spheres with centers  $A$ ,  $B$ ,  $C$ ,  $D$  and radii  $AA'$ ,  $BB'$ ,  $CC'$ , and  $DD'$ , respectively. Then each plane passing through the midpoint of the segment  $B'C'$ ,  $C'A'$ ,  $A'B'$ ,  $D'A'$ ,  $D'B'$  or  $D'C'$  perpendicular to the segment  $BC$ ,  $CA$ ,  $AB$ ,  $DA$ ,  $DB$  or  $DC$ , respectively, contains the point  $P$  [5, 6]. This hypothesis was proved in 2015 in [3]. We found a fact that is similar to the result of Thébault, but now linking the radical center of four spheres with the insphere and the Monge point of a tetrahedron. To avoid ambiguities, we give here the following definitions.

Let  $T$  be a tetrahedron in the Euclidean space  $\mathbb{E}^3$ . A sphere that touches four faces of the tetrahedron  $T$  is called the *insphere* of  $T$ . There are six planes, each of which passes through the midpoint of the edge of the tetrahedron  $T$  perpendicular to its opposite edge. These six planes have a common point, which is called the *Monge point* of  $T$  [4, 7, 8].

The *power* of a point  $P$  with respect to a sphere  $\omega$  with a center  $O$  and radius  $R$  is the number

$$Pow(\omega, P) = |OP|^2 - R^2.$$

Let  $\omega_1$ ,  $\omega_2$ ,  $\omega_3$ , and  $\omega_4$  be spheres with noncoplanar centers in  $\mathbb{E}^3$ . There exists a unique point that has the same power with respect to each of these spheres. This point is called the *radical center* of the spheres  $\omega_1$ ,  $\omega_2$ ,  $\omega_3$ , and  $\omega_4$  [2, 1].

Figure 1. The contact points  $A'$ ,  $B'$ ,  $C'$ , and  $D'$  of the insphere  $\omega$  with the tetrahedron  $ABCD$ , the sphere  $\omega_b$ , and the points  $I$ ,  $M$ ,  $P$ .

## 2. The main theorem

**Theorem 2.1.** *Let  $\omega$  be the insphere of a tetrahedron  $ABCD$ . Assume that  $\omega$  has the center at a point  $I$  and touches the faces  $(BCD)$ ,  $(CDA)$ ,  $(DAB)$ , and  $(ABC)$  at points  $A'$ ,  $B'$ ,  $C'$ , and  $D'$ , respectively. Denote a sphere with the center  $A$ ,  $B$ ,  $C$  or  $D$  and radius  $AA'$ ,  $BB'$ ,  $CC'$  or, respectively,  $DD'$  by  $\omega_a$ ,  $\omega_b$ ,  $\omega_c$  or  $\omega_d$ , respectively. Let  $M$  be the Monge point of the tetrahedron  $A'B'C'D'$ , and let  $P$  be the reflection of  $I$  with respect to  $M$ . Then point  $P$  is the radical center of the spheres  $\omega_a$ ,  $\omega_b$ ,  $\omega_c$ , and  $\omega_d$ .*

*Proof.* We provide an analytical proof of the theorem by depicting the considered elements of the tetrahedron  $ABCD$  in Figure 1.

Let us introduce a Cartesian coordinate system in the space  $\mathbb{E}^3$  putting the origin to the point  $I$  and selecting the radius  $IA'$  of the insphere  $\omega$  as a unit segment of the first coordinate axis. Assume that the coordinate plane  $(xy)$  contains the point  $B'$ . Using the spherical coordinates for the insphere  $\omega$  (see, for instance, formulae (8), (9), (10) in [9]), we find the following coordinates of the considered points

$$I(0, 0, 0), A'(1, 0, 0), B'(a, a', 0), C'(bc, cb', c'), D'(de, ed', e'), \quad (2.1)$$

where for the real numbers  $a, b, c, d, e, a', b', c', d'$ , and  $e'$  from the segment  $[-1, 1]$  the following conditions hold

$$a' = \sqrt{1 - a^2}, b' = \sqrt{1 - b^2}, c' = \sqrt{1 - c^2}, d' = \sqrt{1 - d^2}, e' = \sqrt{1 - e^2}.$$

The plane, which is orthogonal to the segment  $C'D'$  and passes through the midpoint of the segment  $A'B'$ , has the equation

$$(de - bc)x + (ed' - cb')y + (e' - c')z - \frac{a'(ed' - cb') + (de - bc)(a + 1)}{2} = 0. \quad (2.2)$$

The plane, which is orthogonal to the segment  $B'D'$  and passes through the midpoint of the segment  $A'C'$ , is given by the equation

$$(de - a)x + (ed' - a')y + (e')z + \frac{(bc + 1)(a - de) - c'e' - cb'(ed' - a')}{2} = 0. \quad (2.3)$$

And finally, the plane, which is orthogonal to the segment  $A'D'$  and contains the midpoint of the segment  $B'C'$ , has the equation

$$(de - 1)x + (ed')y + (e')z - \frac{(de - 1)(a + bc) + c'e' + e(a' + cb')d'}{2} = 0. \quad (2.4)$$

Solving the system of Eqs. (2.2), (2.3), and (2.4), we find the coordinates of the Monge point  $M$  of the tetrahedron  $ABCD$ :

$$M \left( \frac{a + de + bc + 1}{2}, \frac{ed' + cb' + a'}{2}, \frac{c' + e'}{2} \right).$$

The point  $P$ , which is the reflection of  $I$  with respect to  $M$ , has the coordinates

$$P(a + de + bc + 1, ed' + a' + cb', c' + e'). \quad (2.5)$$

The planes containing faces of the tetrahedron  $ABCD$  are defined by the following conditions

$$(BCD) \perp IA', \quad A' \in (BCD), \quad (CDA) \perp IB', \quad B' \in (CDA),$$

$$(DAB) \perp IC', \quad C' \in (DAB), \quad (ABC) \perp ID', \quad D' \in (BCD).$$

From these conditions we find the equations of the planes  $(BCD)$ ,  $(CDA)$ ,  $(DAB)$ , and  $(ABC)$ , respectively:

$$x - 1 = 0, \quad (2.6)$$

$$ax + a'y - 1 = 0, \quad (2.7)$$

$$bcx + cb'y + c'z - 1 = 0, \quad (2.8)$$

$$dex + ed'y + e'z - 1 = 0. \quad (2.9)$$

Point  $C$  is the intersection of the planes  $(BCD)$ ,  $(CDA)$ , and  $(ABC)$ . Thus, solving the system of Eqs. (2.6), (2.7), and (2.9), we obtain the coordinates of the point  $C$ :

$$C \left( 1, -\frac{a-1}{a'}, \frac{-dea' + ed'a - ed' + a'}{e'a'} \right). \quad (2.10)$$

From the system of Eqs. (2.6), (2.7), and (2.8), we obtain the coordinates of the point  $D$ :

$$D \left( 1, -\frac{a-1}{a'}, \frac{-bca' + cb'a - cb' + a'}{c'a'} \right). \quad (2.11)$$

Using the points coordinates from (2.1), (2.5), (2.10), and (2.11), we find the power of  $P$  with respect to spheres  $\omega_d$  and  $\omega_c$ , respectively:

$$\begin{aligned} Pow(\omega_d, P) &= d^2(P, D) - d^2(D', D) = (a + de + bc + 1 - 1)^2 \\ &+ \left( ed' + a' + cb' + \frac{a-1}{a'} \right)^2 + \left( c' + e' - \frac{-bca' + cb'a - cb' + a'}{c'a'} \right)^2 \\ &- (de - 1)^2 - \left( ed' + \frac{a-1}{a'} \right)^2 - \left( e' - \frac{-bca' + cb'a - cb' + a'}{c'a'} \right)^2 \\ &= 2a + 2de + 2c'e' + 2bc + 2ea'd' + 2ade + 2ca'b' + 2abc + 2ceb'd' + 2bcde - 3. \end{aligned} \quad (2.12)$$

$$\begin{aligned} Pow(\omega_c, P) &= d^2(P, C) - d^2(C', C) = (a + de + bc + 1 - 1)^2 \\ &+ \left( ed' + a' + cb' + \frac{a-1}{a'} \right)^2 + \left( c' + e' - \frac{-dea' + ed'a - ed' + a'}{e'a'} \right)^2 \\ &- (bc - 1)^2 - \left( cb' + \frac{a-1}{a'} \right)^2 - \left( c' - \frac{-dea' + ed'a - ed' + a'}{e'a'} \right)^2 \\ &= 2a + 2de + 2c'e' + 2bc + 2ea'd' + 2ade + 2ca'b' + 2abc + 2ceb'd' + 2bcde - 3. \end{aligned} \quad (2.13)$$

Expressions (2.12), (2.13) yield the equality  $Pow(\omega_d, P) = Pow(\omega_c, P)$ . Taking into account that the vertices of the tetrahedron  $ABCD$  in the proof of this fact are chosen arbitrarily, we conclude that the power of the point  $P$  with respect to each of spheres  $\omega_a$ ,  $\omega_b$ ,  $\omega_c$ , and  $\omega_d$  has the same value.

This completes the theorem proof.  $\square$

### 3. Conclusion

The content of this paper deal with objects in the three-dimensional Euclidean space. Nevertheless, we believe that similar results for simplexes also exist in the Euclidean space  $\mathbb{E}^n$  of any dimension  $n$ . The concept of Monge point in a simplex can be defined as follows.

Let  $F$  be a simplex in the space  $\mathbb{E}^n$ . All hyperplanes, each of which passes through the centroid of a  $(n - 2)$ -face of  $F$  and perpendicular to the opposite edge of this face, have a common point. This point is called the *Monge point* of the simplex  $F$  [4].

We present the following conjecture.

**Conjecture.** Let  $\omega$  be the insphere of a simplex  $A_0A_1 \dots A_n$  in the space  $\mathbb{E}^n$ . Denote the centre of  $\omega$  by  $I$ , and for  $i = \overline{0, n}$ , denote the tangency point of  $\omega$  with the face  $(A_0A_1 \dots A_{i-1}A_{i+1} \dots A_n)$  by  $B_i$ . Let  $\omega_i$  be the sphere with the center  $A_i$  and radius  $A_iB_i$ , and let  $M$  be the Monge point of simplex  $B_0B_1 \dots B_n$ . Then the radical center of all spheres  $\omega_i$  lies on the line  $IM$ .
