# F_p R - Lineer Çarpık Sabit Devirli Kodlar 

Tülay YILDIRIM<br>Karabük University, Eskipazar Vocational School, Karabük, Turkey

## Öz

Bu makalede, $F_{p} R$ halkası üzerinde skew constacyclic kodlar olarak adlandırılan özel bir doğrusal kod sınıfını olan çalışıyoruz, burada $R=F_{p}+v F_{p}, \quad \mathrm{p}$ tek asal sayıdır ve $v^{2}=v$. Bu kodlar $F_{p}^{m} R^{n}$ halkasının bir alt kümesi olarak tanımlanır. $R$ nin bir $\theta$ otomorfizması için, $R[x, \theta]$ skew polinom halkasının yapısal özelliklerini araştırıyoruz. Ayrıca, $F_{p} R$ halkası üzerinde skew constacyclic kodların üreteç polinomlarını ve Gray görüntülerini belirliyoruz.

Anahtar Kelimeler: Lineer kodlar; Skew polinom halkaları; Skew constacyclic kodlar; Skew devirli kodlar.

## 1. Introduction

Codes over finite rings have attracted considerable interest for several decades. One of the significant class of linear codes is known as cyclic codes. Since cyclic codes have very rich algebraic structures, these codes have been examined by many researchers (Zhu et al. 2010, Siap et al. 2011, Dinh et al 2020).

Recently, Bouncher et al. investigated skew cyclic codes over finite fields (Bouncher et. al 2007). These codes were obtained through non-commutative polynomial rings. They showed that skew cyclic codes have many advantages over well-known linear codes of the same dimension and length. Inspired by this study, there are numerous papers on skew cyclic codes over finite fields. For instance; Gursoy et al. considered skew cyclic codes over $F_{q}+v F_{q}$ (Gursoy et al. 2014). Siap et al. studied skew cyclic codes for arbtrary length and obtained optimal linear codes over finite fields (Siap et al. 2011).

Mixed alphabets were first introduced by Delsarte (Delsarte 1973). Later, many papers over mixed alphabet codes were studied (Aksoy and Caliskan 2021, Li et al. 2021, Dinh et al. 2020, Caliskan et al. 2023). The most striking among these studies is the skew cyclic codes over the mixed alphabets.

#### Abstract

In this paper, we study a special class of linear codes, called skew constacyclic codes, over the ring $F_{p} R$, where $R=F_{p}+v F_{p}$, p is an odd prime number and $v^{2}=v$. These codes are defined as a subset of the ring $F_{p}^{m} R^{n}$. For an automorphism $\theta$ of $R$, we investigate the structural properties of skew polynomial ring $R[x, \theta]$. We also determine the generator polynomials and the Gray images of the skew constacyclic codes over the ring $F_{p} R$.

Keywords: Linear codes; Skew polynomial rings; Skew constacyclic codes; Skew cyclic codes.

Benbelkacem et al. considered skew cyclic codes over $F_{4} R$ (Benhelkacem et al. 2022). Li, Gao and Fu presented linear skew cyclic codes on $F_{q} R$ (Li et al. 2021). Besides, Abualrub and Aydin introduced skew cyclic codes over $F_{2}+v F_{2}$ (Abualrub and Aydin 2012). Gao defined skew cyclic codes over $F_{p}+v F_{p}$ and showed that obtained results are equivalent to either cyclic codes or quasi-cyclic codes (Gao 2013). As a generalization of skew cyclic codes, skew constacyclic codes over various rings have been widely studied (Jitman and Ling 2012, Li et al. 2020, Melakhesson et al. 2019). Al- Ashker et al. studied skew constacyclic codes over $F_{p}+v F_{p}$ (Al-Ashker et al. 2021). Melakhesson et al. defined linear skew constacyclic codes over $Z_{q}\left(Z_{q}+u Z_{q}\right)$ (Melakhessou et al. 2019).

The aim of this paper is to present and study skew constacyclic codes over the ring $\mathrm{Fp}_{\mathrm{p}} \mathrm{R}$, where p is an odd prime and $R=F_{p}+v F_{p}$ with $v^{2}=v$. The ring $F_{p} R$ is a finite semi-local and not a chain ring. The paper is organized as follows: Section 2 starts with some basic properties of the ring $R$ and give brief description of the linear codes over the ring $R$. Then, it continues by introducing the algebraic structure of skew polynomial rings as well as the basic results of skew constacyclic codes over the ring $R$. In section 3, linear codes are
generalized to the skew constacyclic codes and examine the algebraic structures of these codes. In section 4, we describe the generator polynomials of the linear skew constacyclic codes over the ring $F_{p} R$. In section 5, we determine the Gray images of skew constacyclic codes over the ring $F_{p} R$.

## 2. Preliminaries

Consider the ring $R=F_{p}+v F_{p}$, where $v^{2}=v$ and p is a number of odd prime. The ring $R$ has two maximal ideals which are $\langle v\rangle$ and $\langle 1-v\rangle$ such that both $R /<v>$ and $R /<1-v\rangle$ are isomoprhic to $F_{p}$. These ideals are maximal ideals in the ring $R$. Thus, $R$ is not a chain ring. By the Chinese Remainder Theorem, one gets $R=\langle v\rangle \oplus\langle 1-v\rangle$ (Lac, 2008). So, each element of $R$ can be state as
$a+v b=v d+(1-v) e$,
where $a, b, d, e \in F_{p}$.
A code $C$ of lenght $n$ over $R$ is a non-empty subset of $R^{n}$ and also it is a linear code if it is a submodule of the $R$ module $R^{n}$. If $\left(c_{0}, c_{1}, \ldots, c_{-1}\right) \in C$, then its polynomial representation is defined as $\varrho(C)=\sum_{i=0}^{n-1} c_{i} x^{i}$. In the rest of the paper, we assume that all the codes are linear codes.

The Euclidean inner product on $R$ is defined as
$\langle x, y\rangle=\sum_{i=0}^{n-1} x_{i} y_{i}$,
for $x=\left(x_{0}, x_{1}, \cdots, x_{n-1}\right)$ and $y=\left(y_{0}, y_{1}, \cdots, y_{n-1}\right)$ in $R^{n}$.
The dual code of $C$, denoted by $C^{\perp}$, is also $R$-linear code and defined as
$C^{\perp}=\left\{y \in R^{n} \mid<x, y>=0, \forall x \in C\right\}$.

### 2.1 Skew polynomial rings over $\boldsymbol{R}$

First, we recall the construction of the non-commutative ring $R[x, \theta]$ and some of its basic properties (Gao 2013). The skew polynomial set $R[x, \theta]$ is defined by
$R[x, \theta]=\left\{f(x)=r_{0}+r_{1} x+r_{2} x^{2}+\cdots+r_{n} x^{n}\right\}$,
where $\quad r_{i} \in F_{p}$ for all $i=0,1, \cdots, n$ and the automorphism $\theta$ of $R$ is defined as
$\theta(v d+(1-v) e)=(1-v) d+v e$,
where $d, e \in F_{p}$. Note that $\theta^{2}(r)=r$ for all $r \in R$, and $\theta$ is a ring homomorphism with order 2.

The skew polynomial ring $R[x, \theta]$ is the set of polynomials over the ring $R$ in which the additon is the
usual adddition of polynomials and multiplicaton is defined as
$\left(a x^{i}\right)\left(b x^{i}\right)=a \theta^{i}(b) x^{i+j}$.
Multiplication can be extended to all elements in $R[x, \theta]$ by the laws of distribution and association. If $\theta$ is not an identity automorphism on $R$, then the ring $R[x, \theta]$ is not a commutative ring. Thus, we have the following results:

Theorem 2.1. (Gao 2013). The center $Z([R, \theta])$ of $R[x, \theta]$ is $F_{p}\left[x^{2}\right]$, where 2 is the order of $\theta$.

Corollary 2.2. (Gao 2013). Let $f(x)=x^{n}-1$. Then $f(x) \in Z([R, \theta])$ if and only if $n$ is even.

Let $g(x), f(x) \in[R, \theta]$, then $g(x)$ is called a right (resp. left) divisor of $f(x)$ if there exists $q(x) \in[R, \theta]$ such that $f(x)=q(x) g(x)$ (resp. $f(x)=g(x) q(x))$.

Lemma 2.3. (Gao 2013). Let $f(x), g(x) \in[R, \theta]$ such that the leading coefficient of $g(x)$ is a unit. Then, there exists unique $q(x), r(x) \in[R, \theta]$ such that $f(x)=q(x) g(x)+$ $r(x)$, where $r(x)=0$ or $\operatorname{deg}(r(x))<\operatorname{deg}(g(x))$.

Definition 2.4. Let $\theta$ be an automorphsm of $R$. A code $C$ is an $R$-linear skew cyclic code (or $\theta$-cyclic code) of length $n$ if
(i) $C$ is an $R$-submodule of $R^{n}$,
(ii) $C$ is closed under the $T_{\theta}$-cyclic shift, i.e.,

$$
\begin{equation*}
T_{\theta}(c)=\left(\theta\left(c_{n-1}\right), \theta\left(c_{0}\right), \ldots, \theta\left(c_{n-2}\right)\right) \tag{7}
\end{equation*}
$$

$$
\text { where } c=\left(c_{0}, c_{1}, \ldots, c_{n-1}\right) \in C
$$

Lemma 2.5. (Al-Ashker and Abu-Jazar 2016) Let $\lambda=\alpha+$ $v \beta$ be an element in the ring $R$, then $\lambda$ is a unit of $R$ if and only if $\alpha \neq 0$ and $\alpha+\beta \neq 0$, where $\alpha, \beta \in F_{p}$.

### 2.2 Skew constacyclic codes over $R$

In this part, we firstly introduce definition of skew constacyclic codes and then continue with its basic results over the ring $R$. Since we follow (Al-Ashker and Abu-Jazar 2016), the proofs of the theories will be omitted. Throughout the study, we denote $\alpha+v \beta$ as $\lambda$ for simplicity, where $\alpha, \beta \in F_{p}$.

Definition 2.6. A subset $C$ of $R^{n}$ is called skew constacyclic code, or $(\theta, \lambda)$-constacyclic code of length $n$ over $R$ if
(i) $C$ is an $R$-submodule of $R^{n}$,
(ii) $C$ is closed under the skew constacyclic shift, i.e.,
$T_{\theta, \lambda}(c)=\left(\lambda \theta\left(c_{n-1}\right), \theta\left(c_{0}\right), \ldots, \theta\left(c_{n-2}\right)\right)$,
where $\lambda$ is unit in $R$ and $c=\left(c_{0}, c_{1}, \ldots, c_{n-1}\right) \in C$.
In particular, if $\lambda$ is 1 or -1 , then $C$ is a skew-cyclic code or skew negacyclic code over $R$, respectively.

In general, a code $C$ of lenght n over $R$ is skew constacyclic code if and only if $\varrho(C)$ is an ideal of $\left.R[x] /<x^{n}-\lambda\right\rangle$. Thus, skew constacyclic code can be define as left ideals in $[R, \theta] /<x^{n}-\lambda>$.

Theorem 2.7. (Al-Ashker and Abu-Jazar 2016). A code C of lenght n over $R$ is skew constacyclic if and only if the skew polynomial representaton of $C$ is a left ideal in $[R, \theta] /<x^{n}-\lambda>$.

## 3. $\boldsymbol{F}_{\boldsymbol{p}} \boldsymbol{R}$-Linear Skew Constacyclic Codes

In this section, we generalize our studies to the skew constacyclic codes over the ring $F_{p} R$.

## Definition 3.1. Define

$F_{p} R=\left\{(d, a+v b) \mid d \in F_{p},(a+v b) \in R\right\}$.
Let $C$ be a skew cyclic code over $F_{p} R$ and m (resp. $n$ ) is the set of $F_{p}$ (resp. $R$ ) coordnate positons.

Throughout the paper, we assume that m and $n$ are odd positive integers.

Any codeword $c \in C$ has the form
$c=\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right) \in F_{p}{ }^{m} R^{n}$.
For $e_{i}=\left(a_{i}+v b_{i}\right)$ for all $i=0,1, \ldots, n-1$.
The ring homomorphism map is defned as
$\delta: R \rightarrow F_{p}$
$a+v b \mapsto a$
For any $r \in R$, a scalar multiplication $*$ defined by
$r *(d, a+v b)=(\delta(r) a, r(a+v b))$,
where $d \in F_{p}$ and $a+v b \in R$. It inherently extends to $F_{p}{ }^{m} R^{n}$ as follows:
$r * x=\left(\delta(r) d_{0}, \delta(r) d_{1}, \ldots, \delta(r) d_{m-1}, r e_{0}\right.$,
$\left.r e_{1}, \ldots, r e_{n-1}\right)$,
where $\mathrm{x}=\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right) \in F_{p}{ }^{m} R^{n}$ for $m, n \in \mathbb{N}$.

A non-empty subset $C$ of $F_{p}{ }^{m} R^{n}$ is called $F_{p} R$-linear code if $C$ is an $R$-submodule of $F_{p}{ }^{m} R^{n}$.

Lemma 3.2. The set $F_{p}{ }^{m} R^{n}$ is an $R$-module with respect to the addition and scalar multiplcation.

Proof. Clear.
Definiton 3.3. The Euclidean inner product over the ring $F_{p}{ }^{m} R^{n}$ is defined as
$<x, y>=v \sum_{i=0}^{m-1} x_{i} y_{i}+\sum_{j=0}^{n-1} x_{i}^{\prime} y_{i}^{\prime}$,
where $x=\left(x_{0}, x_{1}, \ldots, x_{m-1}, x_{0}^{\prime}, x_{1}^{\prime}, \ldots, x_{n-1}^{\prime}\right)$ and $y=$ $\left(y_{0}, y_{1}, \ldots, y_{m-1}, y_{0}^{\prime}, y_{1}^{\prime}, \ldots, y_{n-1}^{\prime}\right)$ in $F_{p}{ }^{m} R^{n}$.

The dual code of $C$ is also $F_{p} R$-linear and defined as
$C^{\perp}=\left\{y \in F_{p}{ }^{m} R^{n} \mid<x, y>=0, \forall x \in C\right\}$.
Definition 3.4. Let $\psi$ be an automorphism of the finite field $F_{p}$. For any two elements $a x^{i}, b x^{j} \in F[x$, $\psi]$, multiplication is defined as
$\left(a x^{i}\right)\left(b x^{j}\right)=a \psi^{i}(b) x^{i+j}$.
In polynomial representation, a linear code of lenght $m$ over $F_{p}$ is a skew constacyclic code if and only if it is a left $F_{p}[x, \psi]$-submodule of $F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>$.
For shortly, $R_{m, n}:=F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>\times R[x, \theta] /<$ $x^{n}-\lambda>$.

We can define the polynomial representation of each codeword of skew constacylic codes as follows:

Definition.3.5. An element
$\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right) \in F_{p}{ }^{m} R^{n}$
can be defined with a module element consisting of two polynomials:
$c(x)=(d(x), e(x)) \in R_{m, n}$,
where $d(x)=d_{0}+d_{1} x+\cdots+d_{m-1} x^{m-1}$ and $e(x)=$ $e_{0}+e_{1} x+\cdots+e_{n-1} x^{n-1}$.

Let $\quad f(x)=f_{0}+f_{1} x+\cdots+f_{s} x^{s} \in[R, \theta] \quad$ and $(d(x), e(x)) \in R_{m, n}$, then multiplication operator on $F_{p} R$ is defined as
$f(x) *(\mathrm{~d}(\mathrm{x}), \mathrm{e}(\mathrm{x}))=(\delta(f(x)) d(x), f(x) * e(x))$,
where $\delta(f(x))=\delta\left(f_{0}\right)+\delta\left(f_{1}\right) x+\cdots+\delta\left(f_{s}\right) x^{s}$. This multiplication is well-defined on $R_{m, n}$. Also, $\delta(f(x)) d(x)$ and $\mathrm{f}(x) * e(x)$ are defined in $F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>$ and $R[x, \theta] /<x^{n}-\lambda>$, respectively.

Lemma 3.6. $R_{m, n}$ is a left $R[x, \theta]$-module under the * multiplcation.

Proof. Clear.
Now, we are ready to introduce the skew constacyclic codes over the ring $F_{p}{ }^{m} R^{n}$.

Definition 3.7. Let $\theta$ and $\psi$ be automorphsms of $R$ and $F_{p}$, respectively. A linear code $C$ over $F_{p}{ }^{m} R^{n}$ is called skew constacyclic code if
(i) $C$ is an $F_{p} R$-submodule of $F_{p}{ }^{m} R^{n}$,
(ii) $C$ is closed under the skew constacyclic shift, i.e.,

$$
\begin{align*}
& S_{\theta, \lambda}(c)=\left(\delta(\lambda) \psi\left(d_{m-1}\right), \psi\left(d_{0}\right), \ldots, \psi\left(d_{m-2}\right)\right. \\
& \left.\lambda \theta\left(e_{n-1}\right), \theta\left(e_{0}\right), \ldots, \theta\left(e_{n-2}\right)\right) \tag{20}
\end{align*}
$$

where $\lambda$ is unit in $R \quad$ and $c=$ $\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right) \in C$.
Lemma 3.8. Let $C$ be a code over $F_{p} R$ with lenght $m+n . C$ is skew constacyclic code if and only if $C$ is a left $R[x, \theta]$-submodule of $R_{m, n}$.

Proof. Let $C$ be a skew constacyclic code over $F_{p} R$ and $c=\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right) \in C$, such that $c(x)=(d(x), e(x))$ be a codeword of $R_{m, n}$. Then
$x * c(x)=\left(\delta(\lambda) \psi\left(d_{m-1}\right)+\right.$
$\psi\left(d_{0}\right) x+\ldots+\psi\left(d_{m-2}\right) x^{m-1}, \lambda \theta\left(e_{n-1}\right)+\theta\left(e_{0}\right) x+$
$\left.\ldots+\theta\left(e_{n-2}\right) x^{n-1}\right) \in C$
Also, $x^{2} * c(x) \in C$ and so on. Since $C$ is a linear code, one gets $\mathrm{f}(\mathrm{x}) * c(x) \in C$, for any $f(x) \in R[x, \theta]$. Thus, $C$ is a left $R[x, \theta]$-submodule of $R_{m, n}$.

On the other hand, assume that $C$ is a left $R[x, \theta]$ submodule of $R_{m, n}$, then for any $c(x) \in C$, we have $x^{i} *$ $c(x) \in C, i \in \mathbb{N}$. Hence, $C$ is a skew constacyclic code.

Let $C$ be a linear code over $F_{p} R$ with length $m+n$. Then $C$ is called seperable if $C=C_{m} \times C_{n}$, while considering $C_{m}$ and $C_{n}$ as punctures codes of $C$ by erasing the coordinates outside the $m$ and $n$ components, respectively. If $C=C_{m} \times C_{n}$ is seperable, then $C^{\perp}=C_{m}^{\perp} \times$ $C_{n}^{\perp}$.

Theorem 3.9. Let $C=C_{m} \times C_{n}$ be a linear code over $F_{p} R$, where $C_{m}$ and $C_{n}$ are linear codes over $F_{p}$ (with length $m$ ) and $R$ (with length $n$ ), respectively. Then, $C$ is a skew constacyclic code if and only if $C_{m}$ is a $\delta(\lambda)$ constacyclic code over $F_{p}$ and $C_{n}$ is a skew $\lambda$-constacyclic code over $R$.

Proof. Let $\left(d_{0}, d_{1}, \ldots, d_{m-1}\right) \in C_{m}$ and $\left(e_{0}, e_{1}, \ldots, e_{n-1}\right) \in$ $C_{n}$. Asume that $C$ is a skew constacyclic code, then we have
$\left(\delta(\lambda) \psi\left(d_{m-1}\right), \psi\left(d_{0}\right), \ldots, \psi\left(d_{m-2}\right)\right.$,
$\left.\lambda \theta\left(e_{n-1}\right), \theta\left(e_{0}\right), \ldots, \theta\left(e_{n-2}\right)\right) \in C$.
Thus, $\quad\left(\delta(\lambda) \psi\left(d_{m-1}\right), \psi\left(d_{0}\right), \ldots, \psi\left(d_{m-2}\right)\right) \in C_{m} \quad$ and $\left(\lambda \theta\left(e_{n-1}\right), \theta\left(e_{0}\right), \ldots, \theta\left(e_{n-2}\right)\right) \in C_{n}$, as desired.

Conversely, by the hypothesis we have $\left(\delta(\lambda) \psi\left(d_{m-1}\right), \psi\left(d_{0}\right), \ldots, \psi\left(d_{m-2}\right)\right) \in C_{m} \quad$ and $\left(\lambda \theta\left(e_{n-1}\right), \theta\left(e_{0}\right), \ldots, \theta\left(e_{n-2}\right)\right) \in C_{n}$. Since $C=C_{m} \times C_{n}$, the proof holds.

## 4. The Generator Set For $\boldsymbol{F}_{\boldsymbol{p}} \boldsymbol{R}$ Skew Constacyclic Codes

Let $C_{1}$ and $C_{2}$ be two linear codes over $F_{p}$ and defined as
$C_{1}=\left\{a \in F_{p}^{m} \left\lvert\, \begin{array}{c}(1-v) b+v a \in C, \\ \text { for some } b \in F_{p}^{m}\end{array}\right.\right\}$,
and
$C_{2}=\left\{b \in F_{p}^{m} \left\lvert\, \begin{array}{c}(1-v) b+v a \in C, \\ \text { for some } a \in F_{p}^{m}\end{array}\right.\right\}$.
So, $C$ can be uniquely state as $C=v C_{1} \oplus(1-v) C_{2}$ (AIAshker and Abu-Jazar 2016). Also, $F_{p} R$ is a non-zero left ideal in $R[x, \theta] /<x^{n}-\lambda>$. In this section, we consider $f_{i}(x)(i=1,2)$ as a set of all non-zero skew polynomials with minimal degree in $F_{p}$.

Theorem 4.1. (Al-Ashker and Abu-Jazar 2016) Let C be a $\lambda$ - constacyclic code over $R$ of length n . If $\quad C=<$ $v f_{1}(x),(1-v) f_{2}(x)>$ with $f_{1}(x) \mid\left(x^{n}-(\alpha+\beta)\right)$ and $f_{2}(x) \mid\left(x^{n}-\alpha\right)$, then $C_{1}=<f_{1}(x)>\quad$ and $\quad C_{2}=<$ $f_{2}(x)>$.

Theorem 4.2. Let $C$ be a linear skew constacyclic code of lenght $m+n$ over $F_{p} R$. Then,
$C=<(g(x), 0),(j(x), h(x))>$,
where $\quad g(x) \mid\left(x^{m}-\delta(\lambda)\right), h(x)=v f_{1}(x)+(1-$ v) $f_{2}(x)$ with $f_{1}(x) \mid\left(x^{n}-(\alpha+\beta)\right)$ and $f_{2}(x) \mid\left(x^{n}-\alpha\right)$.

Proof. Let $C$ be an $F_{p} R$-linaer skew constacyclic code of lenght $m+n$. Define
$\omega: C \rightarrow R[x, \theta] /<x^{n}-\lambda>$
$\left(f_{1}(x), f_{2}(x)\right) \mapsto f_{2}(x)$,
where $f_{1}(x) \in F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>$ and $f_{2}(x) \in$ $R[x, \theta] /<x^{n}-\lambda>$. For any $r(x) \in R[x, \theta]$, one has $\omega\left(r(x) *\left(f_{1}(x), f_{2}(x)\right)\right)=r(x) * \omega\left(f_{1}(x), f_{2}(x)\right)$. So, $\omega$ is a left $R[x, \theta]$-module homomorphism whose image is a left $R[x, \theta]$-submodule of $R[x, \theta] /<x^{n}-\lambda>$. By Lemma 3.8 and Theorem 4.1, we have $\omega(C)=<h(x)>$ $=<f_{1}(x)+(1-v) f_{2}(x)>$ with $f_{1}(x) \mid\left(x^{n}-(\alpha+\beta)\right)$ and $f_{2}(x) \mid\left(x^{n}-\alpha\right)$. Define a set $I$ as

$$
\begin{equation*}
I=\left\{g(x) \in F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>\mid(g(x), 0) \in\right. \tag{27}
\end{equation*}
$$

$\operatorname{ker}(\omega)\}$.
Obviously, $I$ is an ideal of $F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>$. Thus, $I$ is a cyclic code in $F_{p}[\mathrm{x}, \psi] /<x^{m}-\delta(\lambda)>$ which implies that $I=<g(x)>$, where $g(x)$ is a divisor of
$x^{m}-\delta(\lambda)$. For any element $(k(x), 0) \in \operatorname{ker}(\omega)$, one has $k(x) \in I=<g(x)>$. So, there exists a polynomial $l(x) \in R[x, \theta]$ such that $k(x)=\delta(l(x)) g(x)$. Thus, $(k(x), 0)=l(x) *(g(x), 0)$ and this implies that $\operatorname{ker}(\omega)$ is a submodule of $C$ generated by an element of the form $(g(x), 0)$, such that $\operatorname{ker}(\omega)=\langle(g(x), 0)\rangle$, where $g(x) \in F_{p}[\mathrm{x}, \psi]$ and $g(x) \mid\left(x^{m}-\delta(\lambda)\right)$. By the first isomorphism theorem,
$C / \operatorname{ker}(\omega) \cong<h(x)>$.
Let $\quad(j(x), h(x)) \in C \quad$ such that $\omega(j(x), h(x))=$ $h(x)$. Then, $C$ can be generated as a left $R[x, \theta]$ submodule of $R_{m, n}$ by two elements of the form
$((g(x), 0))$ and $(j(x), h(x))$. So, any element in $C$ can be written as
$r_{1}(x) *((g(x), 0))+r_{1}(x) *(j(x), h(x))$,
where $r_{1}(x), r_{2}(x) \in R[x, \theta]$. Hence,
$C=<(g(x), 0),(j(x), h(x))>$,
where $\quad g(x) \mid\left(x^{m}-\delta(\lambda)\right), h(x)=v f_{1}(x)+(1-$ v) $f_{2}(x)$ with $f_{1}(x) \mid\left(x^{n}-(\alpha+\beta)\right)$ and $f_{2}(x) \mid\left(x^{n}-\alpha\right)$.

Lemma.4.3. If $C=<(g(x), 0),(j(x), h(x))>$ is a linear skew constacyclic code of lenght $m+n$ over $F_{p} R$, then $\operatorname{deg}(j(x))<\operatorname{deg}(g(x))$.

Proof. Assume that $\operatorname{deg}(j(x)) \geq \operatorname{deg}(g(x))$ and $\operatorname{deg}(j(x)-g(x))=s \in \mathbb{N}$. Let
$D=<(g(x), 0),\left(j(x)-x^{s} g(x), h(x)\right)>$.
Then, one gets $D \sqsubseteq C$. Also,
$\left.(j(x), h(x))=\left(j(x)-x^{s} g(x), h(x)\right)+x^{s} *(g(x), 0)\right)$.
Thus, $C \sqsubseteq D$ and so $D=C$. This implies a contradiction. So, $\operatorname{deg}(j(x))<\operatorname{deg}(g(x))$.

## 5. Gray Images of Skew Constacyclic Codes Over $\boldsymbol{F}_{\boldsymbol{p}} \boldsymbol{R}$

The Gray map between $F_{p} R$ and $F_{p}{ }^{3}$ is defined as

$$
\begin{align*}
& \zeta: F_{p} R \rightarrow F_{p}^{3} \\
& \zeta((d, a+v b))=(d,-b, 2 a+b), \tag{32}
\end{align*}
$$

where $(d, a+v b) \in F_{p} R$. This map can be extended to the map $\zeta: F_{p}{ }^{m} R^{n} \rightarrow F_{p}{ }^{m+2 n}$ such that

$$
\zeta\left(\left(d_{0}, d_{1}, \ldots, d_{m-1}, a_{0}+v b_{0}, a_{1}+v b_{1}, \ldots, a_{n-1}+\right.\right.
$$

$\left.\left.v b_{n-1}\right)\right)=\left(d_{0}, d_{1}, \ldots, d_{m-1},-b_{0},-b_{1}, \ldots,-b_{n-1}, 2 a_{0}+\right.$
$\left.b_{0}, 2 a_{1}+b_{1}, \ldots, 2 a_{n-1}+b_{n-1}\right)$,
for all $\left(d_{0}, d_{1}, \ldots, d_{m-1}\right) \in F_{p}{ }^{m}$ and $\left(a_{0}+v b_{0}, a_{1}+\right.$ $\left.v b_{1}, \ldots, a_{n-1}+v b_{n-1}\right) \in R^{n}$.

If $C$ is an $F_{p} R$-linear codes, then $\zeta(C)$ is also $F_{p}$-linear.
The Hamming weight of a codeword $c$ in $F_{p}{ }^{m} R^{n}$ is the number of non-zero coordinates in $c$ and denoted by $w_{H}(c)$. The Hamming distance between two codewords $c_{1}$ and $c_{2}$ in $F_{p}{ }^{m} R^{n}$ is defined as $d_{H}\left(c_{1}, c_{2}\right)=w_{H}\left(c_{1}-\right.$ $c_{2}$ ) and Hammng distance for a code C is defined by $d_{H}(C)=\min \left\{d_{H}\left(c_{1}, c_{2}\right) \mid c_{1} \neq c_{2}, \forall c_{1}, c_{2} \in C\right\}$.

The Lee weight of $(d, a+v b) \in F_{p} R$ can be defined as
$w_{L}((d, a+v b))=w_{H}(d)+w_{H}(-b)+w_{H}(2 a+b)$.
The Lee weigth of a codeword is the rational sum of Lee weigths of its components. The Lee distance between two codewords $c_{1}$ and $c_{2}$ in $F_{p}{ }^{m} R^{n}$ is defined as

$$
\begin{equation*}
d_{L}\left(c_{1}, c_{2}\right)=w_{L}\left(c_{1}-c_{2}\right) \tag{34}
\end{equation*}
$$

Proposition 5.1. The Gray map $\zeta$ is an $F_{p}$-linear distance preserving map from $F_{p}{ }^{m} R^{n}$ to $F_{p}{ }^{m+2 n}$.
Proof. Let $x=\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right)$ and $y=$ $\left(d_{0}^{\prime}, d_{1}^{\prime}, \ldots, d_{m-1}^{\prime}, e_{0}^{\prime}, e_{1}^{\prime}, \ldots, e_{n-1}^{\prime}\right)$ be two elements in $F_{p}{ }^{m} R^{n}$, where $e_{i}=a_{i}+v b_{i}$ and $e_{i}^{\prime}=a_{i}^{\prime}+v b_{i}^{\prime}$ for $i=$ $0,1, \ldots, n-1$. By the definiton,
$\zeta(x+y)=\zeta\left(\left(d_{0}, d_{1}, \ldots, d_{m-1}, e_{0}, e_{1}, \ldots, e_{n-1}\right)+\right.$ $\left.\left(d_{0}^{\prime}, d_{1}^{\prime}, \ldots, d_{m-1}^{\prime}, e_{0}^{\prime}, e_{1}^{\prime}, \ldots, e_{n-1}^{\prime}\right)\right)=\left(d_{0}+\right.$
$d_{0}^{\prime}, d_{1}+d_{1}^{\prime}, \ldots, d_{m-1}+d_{m-1}^{\prime},-b_{0}-b_{0}^{\prime},-b_{1}-$
$b_{1}^{\prime}, \ldots,-b_{n-1}-b_{n-1}^{\prime}, 2\left(a_{0}+a_{0}^{\prime}\right)+b_{0}+$
$b_{0}^{\prime}, \quad 2\left(a_{1}+a_{1}^{\prime}\right)+b_{1}+b_{1}^{\prime}, \ldots, 2\left(a_{n-1}+a_{n-1}^{\prime}\right)+$ $\left.b_{n-1}+b_{n-1}^{\prime},\right)=$
$\left(d_{0}, d_{1}, \ldots, d_{m-1},-b_{0},-b_{1}, \ldots,-b_{n-1}, 2\left(a_{0}+\right.\right.$ $\left.\left.b_{0}\right), 2\left(a_{1}+b_{1}\right), \ldots, 2\left(a_{n-1}+b_{n-1}\right)\right)+$ $\left(d_{0}^{\prime}, d_{1}^{\prime}, \ldots, d_{m-1}^{\prime},-b_{0}^{\prime},-b_{1}^{\prime}, \ldots,-b_{n-1}^{\prime}, 2\left(a_{0}^{\prime}+\right.\right.$ $\left.\left.b_{0}^{\prime}\right), 2\left(a_{1}^{\prime}+b_{1}^{\prime}\right), \ldots, 2\left(a_{n-1}^{\prime}+b_{n-1}^{\prime}\right)\right)=\zeta(x)+$ $\zeta(y)$.

Also, for any element $s \in F_{p}$,

$$
\begin{align*}
& \zeta(s x)=\zeta\left(s d_{0}, s d_{1}, \ldots, s d_{m-1}, s e_{0}, s e_{1}, \ldots, e_{n-1}\right)= \\
& \left(s d_{0}, s d_{1}, \ldots, s d_{m-1},-s b_{0},-s b_{1}, \ldots,-s b_{n-1}, s\left(2 a_{0}+\right.\right. \\
& \left.\left.b_{0}\right), s\left(2 a_{1}+b_{1}\right), \ldots, s\left(2 a_{n-1}+b_{n-1}\right)\right)=s \zeta(x) . \tag{36}
\end{align*}
$$

Hence, $\zeta$ is an $F_{p}$-linear map. Moreover, we can show that $\zeta$ is an $F_{p}$-linear distance preserving map as follows:

$$
\begin{align*}
& d_{L}(x, y)=w_{L}(x-y)=w_{H}\left(d-d^{\prime}\right)+w_{H}(\zeta(e- \\
& \left.\left.e^{\prime}\right)\right)=w_{H}\left(d-d^{\prime}\right)+w_{H}\left(\zeta(e)-\zeta\left(e^{\prime}\right)\right)= \\
& d_{H}\left(d, d^{\prime}\right)+d_{H}\left(\zeta(e), \zeta\left(e^{\prime}\right)\right) \tag{37}
\end{align*}
$$

Corollary 5.2. If $C$ is an $F_{p} R$-linear code with parameters $\left[m+n, M, d_{L}\right]$, then $\zeta(C)$ is a $q$-ary linear code with parameters $\left[m+2 n, \log _{q} M, d_{L}\right]$, where $M$ denotes the number of codewords in $C$.

Proof. Clear.
Theorem 5.3. Let $C$ be a linear code over $F_{p} R$. Then $\zeta\left(C^{\perp}\right)=\zeta(C)^{\perp}$.
Proof. Let $c_{1}=\left(d_{1}, a_{1}+v b_{1}\right) \in C$ and $c_{2}=\left(d_{2}, a_{2}+\right.$ $\left.v b_{2}\right) \in C^{\perp}$. By the definiton, one gets $d_{1} d_{2}=a_{1} a_{2}=$ $a_{1} b_{2}+a_{2} b_{1}+b_{1} b_{2}=0$. Thus,

$$
\begin{gather*}
<\zeta\left(c_{1}\right), \zeta\left(c_{1}\right)>=<\left(d_{1},-b_{1}, 2 a_{1}+\right. \\
\left.b_{1}\right),\left(d_{2},-b_{2}, 2 a_{2}+b_{2}\right)>=d_{1} d_{2}+4 a_{1} a_{2}+2\left(a_{1} b_{2}+\right. \\
\left.a_{2} b_{1}+b_{1} b_{2}\right)=0 . \tag{38}
\end{gather*}
$$

Hence, $\zeta\left(c_{2}\right) \in C^{\perp}$ and this gives that $\zeta\left(C^{\perp}\right) \subseteq \zeta(C)^{\perp}$. Since $F_{p} R$ is a Frobeniues ring,
$\left|\zeta\left(C^{\perp}\right)\right|=\frac{p^{m+2 n}}{|\zeta(C)|}=\frac{p^{m+2 n}}{|C|}=\left|C^{\perp}\right|$,
and the result follows.

If a code $C$ is equal to its dual, then $C$ is called self-dual code.

Corollary 5.4. Let C be a linear code over $F_{p} R$. If C is a self-dual code, so is $\zeta(C)$.
Proof. Clear.
