Photo-Isomerization and Decarboxilation of 2-Amino-5-Chlorobenzoic Acid in Argon Matrix

Nihal KUŞ*

Araştırma Makalesi/Research Article

Abstract- In this work, 2-amino-5-chlorobenzoic acid (ACIBA) was studied for the first time using matrix isolation spectroscopy in solid argon matrix at 15 K. The molecule has four different conformers, differing by internal rotation about the C–C and C–O bonds. The lowest energy form (O=C–C–C dihedral angle of 0°) was experimentally observed in the IR spectra of the as-deposited ACIBA matrices. UV irradiation at λ > 234 nm of the matrix-isolated compound was found to lead to conversion of this conformer into the other conformers and also to decarboxylation of the compound, with production of CO₂. The data of the experimental infrared spectrum results on matrix isolated ACIBA were compared with theoretical calculated results.

Keywords- Matrix isolation IR spectroscopy, 2-Amino-5-Chlorobenzoic Acid, Photoisomerization, Decarboxylation.

I. INTRODUCTION

Benzonic acid is a colorless and one of the simplest aromatic compound containing one monocyclic ring with carboxylic acid group. It is mostly used for food preservative and treatment of certain diseases, for instance, fungus, acne, and tinea [1]. Low temperature matrix isolation infrared spectra of benzoic acid monomers and dimers in argon were studied by Reva and his co-workers. They found that molecule had two conformers with syn and anti form and also, they investigated hydrogen bond interactions by annealing the molecule [2, 3]. 2-chlorobenzoic acid molecule, a derivative of benzoic acid, was examined by matrix isolation spectroscopy and two conformations were found in two different cis positions [4]. UV-induced stimulation of the matrix isolated α-ketocarboxylic acid molecule resulted in less stable conformation with the hydrogen tunneling [5].

Decarboxylation was observed in many matrix isolation experiments. α-pyron was one of the first low temperature studies investigated by the research groups, using matrix isolation spectroscopy [6-9]. As a result of photochemistry of α-pyron, aldehyde ketene (open ring), dewar isomer and decarboxilation of compound were observed and investigated (Figure 1).

![Figure 1. Photochemistry channel of α-pyron](image)

In our previous study, 2-Chloro-6-fluorobenzoic acid molecule was studied by matrix isolation method. Three different conformers were found depending on the location of the CCOH group. The formation of decarboxylation was achieved with sufficient amount of UV irradiation. 1-chloro-3-fluorobenzene molecule was observed with CO₂ [10] as a photoproducts. Another decarboxilation reaction was observed in matrix isolated serine molecule. When compound was exposed to UV irradiation (λ > 200 nm), CO₂ was observed around 2340 cm⁻¹ and also other photogenerated species [11, 12]. As a result of photodecomposition of phenylalanine molecule, the CO₂ product and phenethylamine were observed [13]. Upon laser/MOPO irradiation at 335 and

345 nm to the matrix isolated N-Salicylidene-p-carboxyaniline, one of the photo products was CO$_2$. Furthermore, experimental process, decarbonylation reaction occurred and CO characteristic band was observed about 2130 cm$^{-1}$ spectral region [14].

In this study, matrix isolation experiments of 2-amino-5-chlorobenzoic acid were done based on the principle of trapping molecules into the cell part of the matrix cage without reaction with inert gas. The best of our knowledge, ACIBA was studied for the first time by low temperature spectroscopy in argon matrix at 15 K. No data have been reported about the photochemistry of ACIBA. UV irradiation at $\lambda > 234$ nm of the matrix-isolated molecule was resulted in the conversion of into the other less stable conformers and also to decarboxylation of the molecule, with production of CO$_2$ and 2-amino-5-chlorobenzene (ACIB), whose vibrational frequencies could be identified in the spectra of the UV-irradiated matrix. The analysis of the experimental data on matrix isolated ACIBA was supported by extensive quantum chemical calculations.

II. PHOTOCHEMISTRY OF ISOLATED ACIBA IN ARGON MATRIX

In this study, photochemistry of monomeric ACIBA in low temperature matrix was focused and interpreted. Matrix isolation experiments were achieved in Laboratory for Molecular Cryospectroscopy and Biospectroscopy (LMCB) at Coimbra University. The argon matrix was prepared by codeposition of ACIBA vapors with nitrogen onto the cold CsI window of the cryostat (15 K). The infrared spectra were taken in the range of 4000−400 cm$^{-1}$. Compound deposition was finished when the matrix reached a sufficient thickness. The matrix was irradiated with a power of 300 W of 500 W Hg(Xe) arc lamp and recorded after 3, 6, 9, 12, and 15 min of irradiation. When compound was completely deposited in argon at 15 K, only most stable conformer was appeared in the argon matrix spectrum. The other three conformations with high energy were observed after UV irradiation with $\lambda > 234$ nm.

The equilibrium geometries of the ACIBA molecule and the optimizations of the photo products were run by Gaussian 09 programme [15] using split valans triple zeta basic set density functional theory (DFT) with the 6-311++G(d,p) basis set [16, 17]. The B3LYP density functional theory, which is the three-parameter used for the calculation of DFT, gradient change correlation of Becke (Becke, 1988) and Lee, Yang, Parr [18–20] was used successfully. Potential energy profile allowed us to obtain four different conformers of the ACIBA by interconversion between C-C and C-O bounds. Conformer (I) was computed to be more stable than the other forms by 12.3 (C–C–C≡C dihedral angle is 177.8°), 29.1 (C–C–O–H dihedral angle is 10.4°) and 38.0 kJ mol$^{-1}$ (C–C–O–H dihedral angle is 356°) with zero point vibrational energy (ZPE), respectively.

Figure 3. Optimized geometry at DFT(B3LYP)/6-311++G(d,p) of ACIBA (most stable form) with symbols and its conformers.

Relative energies and dipole moments of all conformers of the ACIBA are given in Table 1. As seen in the table, relative energies and the dipole moment of the conformer IV was found to be higher than other conformations.

The B3LYP/6-311++G(d,p) calculated barrier energies of the conformations are shown in Figure 4. The calculated barrier energy resulting from rotation around the C-C bound was 46.3 kJ mol⁻¹, for reverse processing it was 33.9 kJ mol⁻¹ (Figure 3-a). The barrier energies between conformers I → III, II→III and III→IV were calculated 49.7, 51.7 and 26.5 kJ mol⁻¹, respectively. In case of reverse barrier energies were 20.2, 27.7 and 19.7 kJ mol⁻¹, respectively (Figure 3-b, c, d).

Matrix-isolated ACIBA was exposed to UV-irradiations with different cut-off filters (λ > 375, 337, 283, 234 nm) or directly to the quartz window. There was not observed any changes in the spectrum while molecule was irradiated with λ > 375, 337, 283 nm. The energy given by UV irradiation was sufficient and since the electrons in the molecule were excited from the ground state to the excited state. However, changes started to occur when the sample was irradiated with λ > 234 nm. Quantum chemical calculations were used to analyze the spectra for all conformers. After comparing the experimental and calculated spectra, the experimentally observed spectra were determined to belong to the other three conformers II, III and IV (Figure 5 and 6, Table 2). In this case, some of the spectra intensity decreased while the others increased.

Frequencies (ν) in cm⁻¹; calculated infrared intensities in km mol⁻¹; ν, stretching, δ, in-plane bending, n.obs., not observed, see Figure 1 for atom numbers of ACIBA.

Figure 5. C=O spectral region for deposited compound in argon matrix; UV-irradiated with λ>234 nm and calculated spectra for conformers I, II, III and IV.

Experimental matrix isolation (deposited and UV-irradiated) spectra and calculated spectra (1800-1400 cm⁻¹ spectral region) are given in Table 2. In the table, only the spectral region with a high intensity was taken. It shows that all the conformers are trapped within the argon matrix at 15 K. As can be seen in Figure 5 and Table 2, the C=O region can be compared in detail.

ν, stretching, δ, in-plane bending, see Figure 6 for ACIB and CO₂.
The most intense band of CO$_2$ was observed experimentally at 2345 cm$^{-1}$ and calculated computationally at 2365 cm$^{-1}$ (Table 2, Figure 5). Calculated ACIB and CO$_2$ spectrum fits well with the experimentally observed one.
Frequency analysis of the conformers were performed using the data obtained from the result of output file of the Gaussian Program. The results of the analysis are given in Table 2. Upon UV irradiation matrix-isolated compound has been shown directly to quartz, the started to decompose, with evolution of CO\textsubscript{2} and formation of 2-amino-5-chlorobenzene (Figure 7, Table 2).
In our previous work, matrix isolated coumarin in argon was exposed to UV-irradiation (λ > 200 nm). Decarboxylation of the molecule was observed and products of benzocyclobutadiene and CO₂ [21]. However, in 3-acetamido-coumarin only the open-ring ketene and the decarbonylation reactions were shown in the matrix spectra, while Dewar isomer photoproduct was not occur [22]. Similar results were observed for 2-pyrene-3-carboxylate [23]. UV-irradiation (λ > 234 nm) of the matrix isolated 3-furaldehyde was analysed and resulted in conformational change. When compound was irradiated at higher energy directly to the quartz window, decarbonylation of the compound was observed with products of two C₃H₄ isomers (cyclopentene and propadiene), furan, and cyclopropene-3-carbaldehyde [24].

Calculated infrared spectrum by the B3LYP/6-311++G(d,p) for ACIB fit very well with the experimental UV irradiated matrix isolated compound, both concerning intensities and relative position of bands (Figure 6). Before UV irradiation experiments between 7000-2000 cm⁻¹, compound was irradiated with near infrared (NIR) light and overtone (2νO-H) band appeared on the NIR spectra about 6100 cm⁻¹ spectral region. The aim was to obtain other conformations of ACIBA by exciting the OH band. However, no changes in the spectrum was observed.

The Spectra with different intensities at different regions were observed after 3 min. in the matrix. Every step of UV irradiation time was increased by 3 minutes. Density functional theory calculations were carried out to evaluate the experimental and calculated data of photoproducts. New peaks appeared with decarboxilation in the spectrum when matrix isolated ACIBA was irradiated with UV light just for 3 minutes. The difference spectrum (matrix isolated spectra minus UV-irradiated spectra) of products (Figure 7) were compared with the calculated spectra of ACIB. In the calculated results, it was proved that strong CO₂ absorption bands between 2348-2336 cm⁻¹ spectral region were in the same region at UV-induced matrix experiment (Figure 8).
III. CONCLUSIONS

In this work, experimental studies of ACIBA were performed by matrix isolation infrared spectroscopy in solid argon. The spectra of the four conformations were observed after the molecule was deposited in the solid argon. In order to obtain optimized molecule, ab-initio quantum chemical calculations were made on the computer using DFT method and B3LYP hybrid functional with 6-311++G(d,p) basis set. The minimum energies of the four conformers were found from the potential energy calculation results and their infrared spectra were plotted to compare with the experimental results. Four different conformers were observed using in situ UV irradiations (λ>234 nm) in a low temperature (15 K) argon matrix spectra. As a result of the decarboxylation reaction, new photo product, ACIB and CO\(_2\) were observed at the same time with conformers. The results of the experiment were well matched to the calculations. The experiment thought to be repeated in the future, using NIR light sources in the nitrogen or xenon matrices to investigate if different photoproducts can be formed.

ACKNOWLEDGMENT

I trully appreciate all the help of Prof. Dr. Rui Fausto also giving opportunity to do matrix isolation experiments in LMCB laboratory of Coimbra University.
