Temperature-
dependent material
properties; Finite
element method**Abstract**

Nonlinear vibrations of composite plates on an elastic foundation in thermal environments are presented in this study. Graphite/epoxy is selected as the plate material. The properties of composite material are assumed to be temperature-dependent. Nonlinear free vibrations of laminated composite plates are investigated in the fully clamped boundary conditions. The classical finite element method is used and a specially prepared computer code is written in the Matlab software. Vibrations of the spring supported laminated composite plate are directly influenced by the boundary conditions and dimensions of plate. In this study, generated graphical values reveal that foundation stiffness and temperature have significant effects on the linear and nonlinear frequencies of composite plates.

Termal Ortamda Elastik Tabandaki Kompozit Plakaların Doğrusal Olmayan Titreşim Analizi**Özet**

Anahtar kelimeler
Doğrusal olmayan
titreşim; Kompozit
plaka; Elastik taban;
Sıcaklık-malzeme
özelliklerine bağlı; Sonlu
elemanlar metodu

Bu çalışmada termal ortamda elastik tabandaki bir kompozit plakalarında doğrusal olmayan titreşimleri sunulmaktadır. Grafit/epoksi plaka malzemesi olarak seçilmiştir. Kompozit malzeme özellikleri sıcaklık bağımlı olduğu varsayılmaktadır. Lamine kompozit plakalar doğrusal olmayan serbest titreşimleri tam ankastre sınır koşullarında incelenmiştir. Klasik sonlu elemanlar yöntemi kullanılmıştır ve özel olarak hazırlanmış bilgisayar kodu Matlab yazılımıyla hazırlanmıştır. Lamine Kompozit plakaları destekleyen yayların titreşimleri direk olarak sınır koşulları ve plaka boyutlarıyla etkilenmektedir. Bu çalışmada oluşturulan grafik değerlerden, tabandaki sertlik ve sıcaklığın kompozit plakaların doğrusal ve doğrusal olmayan frekanslarına önemli ölçüde etkilerinin olduğu görülmektedir.

1. Introduction

Due to their outstanding properties, sandwich-type constructions are great role in the construction of space vehicles and transportation systems (Wang and Shen 2011). With the development of technology, it is possible to apply composite plates in high-temperatures. Predicting of the thermoelastic response of composite plates is necessary for the development of efficient models (Zhenet *al.* 2010).

Many studies have been presented on the linear and nonlinear free vibration analyzes of composite plates. Thermal affects and elastic foundations are less in these studies. Among those; Wanga and Shen (2013) investigated nonlinear dynamic response of sandwich plates with FGM face sheets resting on elastic foundations in thermal environments. Zenkour and Sobhy (2010) studied thermal buckling of various types of sandwich plates. Shen and Zhu (2012) investigated postbuckling of sandwich plates with nanotube-reinforced composite face sheets resting on elastic

foundations. Sofiyev and Kuruoglu(2013) studied the non-linear buckling of the truncated conical shell made of functionally graded materials (FGMs) surrounded by an elastic medium. Li and Lin (2012) presented thermal postbuckling analysis for shear-deformable anisotropic laminated cylindrical shell of finite length. Xu *et al.*(2013) investigated the nonlinear bending behavior of a bilayer rectangular graphene sheet subjected to a transverse uniform load in thermal environments. Shen (2011) analyzed postbuckling, nonlinear bending and nonlinear vibration analysis of thin film resting on elastic foundation in thermal environments. Zenkour *et al.*(2013) investigated the bending response of an orthotropic rectangular plate resting on two-parameter elastic foundations under thermomechanical loadings. Zhen *et al.*(2010) proposed a new efficient global–local higher-order model for the thermoelastic analysis of laminated composite and sandwich plates. Moore *et al.*(2013) studied thermal response and stability characteristics of bistable composite laminates by considering temperature dependent material properties and resin layers.

In this study, nonlinear vibration analysis of composite plates on elastic foundations in thermal environments is studied. Graphite/epoxy is selected as a plate material. The properties of composite material are assumed to be temperature-dependent. The numerical results showed that the linear and nonlinear vibration characteristics of composite plates on elastic foundations have varied depending on conditions of thermal environment. The classical finite element method is used in the analysis. Also, plate dimensions and boundary conditions have effects on the vibrations of composite plates.

2. Finite Element Method

A rectangular element, which is under the effect of bending vibrations, is shown at Fig. 1. The element mass matrix written according to Fig. 1 is shown in Equation 1. Further detail information has been presented by (Petyt 1990).

$$[M]_e = \frac{\rho h a b}{6300} \begin{bmatrix} m_{11} & m_{21}^T \\ m_{21} & m_{22} \end{bmatrix} \tag{1}$$

Figure 1. Geometry of a rectangular plate model

$[K]_e$ is element stiffness matrix (Morgüland Küçükrendeci2008).

$$[K]_{eNL} = \begin{bmatrix} [K^*]_{11} & & & \text{sym.} \\ [K^*]_{21} & [K^*]_{22} & & \\ [K^*]_{31} & [K^*]_{32} & [K^*]_{33} & \\ [K^*]_{41} & [K^*]_{42} & [K^*]_{43} & [K^*]_{44} \end{bmatrix} \tag{2}$$

The geometrical nonlinear strain energy for the highly displaced systems can be given as

$$U_{NL} = \frac{1}{2} \int_V \{\psi\}^T [\sigma_0] \{\psi\} dV \tag{3}$$

where the matrix $[\sigma_0]$ is axial stresses of the element. $\{\psi\}$ is the nonlinear displacement in the z direction and V is the volume. The terms of the matrix $[\sigma_0]$ are

$$\{\sigma_0\} = [D] \{ \{\epsilon\} - \{\alpha\} \Delta T \}$$

$$\{\epsilon\} = \begin{Bmatrix} \epsilon_x \\ \epsilon_y \end{Bmatrix}, \{\alpha\} = \begin{Bmatrix} \alpha_1 \\ \alpha_2 \end{Bmatrix}, \Delta T = T_2 - T_1 \tag{4}$$

$[D]$ matrix was defined in Morgüland Küçükrendeci (2008). α is thermal expansion coefficient and ΔT is temperature change. Where $\{\epsilon\}$ is the axial displacement. $[\sigma_0]$ and $\{\psi\}$ are defined as

$$[\sigma_0] = \begin{bmatrix} \sigma_x & \tau_{xy} \\ \tau_{xy} & \sigma_y \end{bmatrix} \tag{5}$$

and

$$\{\psi\} = \begin{bmatrix} \frac{\partial w}{\partial x} \\ \frac{\partial w}{\partial y} \end{bmatrix} \tag{6}$$

Equation (5) can be re-defined using the thickness of the plate element.

$$U_{NL} = \frac{1}{2} \int_A h \{\psi\}^T [\sigma_0] \{\psi\} dA \quad (7)$$

Substituting Eq. (1) in Eq. (7) gives

$$U_{eNL} = \frac{1}{2} \{w_*\}^T [K]_{eNL} \{w_*\} \quad (8)$$

Where $\{w_*\}$ is the nonlinear displacement vector. $[K]_{eNL}$ is nonlinear stiffness matrix of the element.

The nonlinear stiffness matrix of the element obtained using Eq. (8). This matrix is in the form of 3x3 square sub-matrix and shown in Eq. (9),

$$[K]_{eNL} = \begin{bmatrix} [K^*]_{11} & & & \text{sym.} \\ [K^*]_{21} & [K^*]_{22} & & \\ [K^*]_{31} & [K^*]_{32} & [K^*]_{33} & \\ [K^*]_{41} & [K^*]_{42} & [K^*]_{43} & [K^*]_{44} \end{bmatrix} \quad (9)$$

3. Nonlinear Vibration Analysis

Eq. (10) is used for free vibration analysis of the laminated composite plates.

$$[M]\{\ddot{u}\} + [K]\{u\} = \{0\} \quad (10)$$

In Eq. (10), $[M]$ and $[K]$ are system mass matrix and system stiffness matrix. System matrix is obtained by combining of elementary matrices.

Natural frequencies “ ω ” and modes of vibration is determined in linear free vibration analysis by solving the eigenvector of structure.

$$([K] - \omega^2 [M]) \{\Phi\} = \{0\} \quad (11)$$

where $\{\Phi\}$ is eigenvector.

$[K^S]$ is spring matrix. $[K^S]$ matrix is added to the $[K]$ matrix and the Eq. (12) is obtained.

$$([K] + [K^S]) - \omega^2 [M] \{\Phi\} = \{0\} \quad (12)$$

Eq. (14) is used for the analysis of linear free vibrations.

The nonlinear free vibration analysis is carried by solving equations of geometrical nonlinearity system. An iteration steps are used for each deformation stage in the solution. Nonlinear free vibration analysis requires a series of operations

(Karadağ and Morgül 1992). The nonlinear element stiffness matrix $[K]_{eNL}$ is given in Eq. (13). $[K]_{NL}$ matrix can be written by the combination of nonlinear elementary stiffness matrices.

$$([K] + [K]_{NL} + [K^S]) - \omega_{NL}^2 [M] \{\Phi_{NL}\} = \{0\} \quad (13)$$

Nonlinear natural frequencies (ω_{NL}) and nonlinear unitvector $\{\Phi_{NL}\}$ are calculated by solution of Eq. (13). The damping factor was not taken into account in the analyzes.

4. Physical Properties of Composite Plates

In this study, flat composite laminated plates are used. The plate models are in the form of rectangular. The dimensions of all the plate models are selected as $a/b=1$ and $a/b=2$. Composite plate is formed by five laminates of overlapping lined up. Laminates are lined up symmetrically as $(\theta, -\theta, \theta, -\theta, \theta)$. θ is orientation angle of laminates. Two different orientation angle are selected in the analyzes. These angles are 30° and 45° . For example, $\theta=30^\circ$; angles of five laminated plates are $30^\circ, -30^\circ, 30^\circ, -30^\circ, 30^\circ$, respectively. Where, the laminates are fiber fabrics and its material is selected as a graphite/epoxy in this study. Temperature dependent mechanical properties of graphite/epoxy are shown in Table 1. The fiber fabrics are placed one on the top with different orientation angles. So that symmetrically laminated composite plate is obtained. The thickness of the fiber fabric layers is chosen as 0.2 mm. So the total thickness of composite plates is $h=1\text{mm}$.

	Temperature ($^\circ\text{C}$)			
	20	200	260	600
E_1 (GPa)	141	141	141	141
E_2 (GPa)	13.1	10.3	0.138	0.0069
G_{12} (GPa)	9.31	7.45	0.069	0.0034
ν_{12}	0.28	0.28	0.28	0.28
ν_{21}	0.026	0.020	0.00027	0.000013
α_1 ($10^{-6}/^\circ\text{C}$)	0.0018	0.054	0.054	0.054
α_2 ($10^{-6}/^\circ\text{C}$)	21.6	37.8	37.8	37.8

Table 1. Temperature dependent mechanical properties of graphite/epoxy (Singha *et al.* 2001)

A fully clamped boundary condition is selected for composite plate models. The spring supports and

the plate dimensions are shown in Fig. 2. Selected spring stiffness values are $k_1=1000$ N/m and $k_2=0$.

Figure 2. Model of spring supported laminated composite plate

5. Numerical Analysis

In Morgüland Küçükrendeci (2008), the boundary conditions of composite plates were also selected as fully clamped. The parameters of natural frequency of the undamped free vibration were calculated according to the Eq. (16). In Hanand Petyt (1996) and Chowet *al.*(1992) frequency parameters were found for composite plates in similar conditions but they have used different analyzes methods. Frequency parameters of Morgüland Küçükrendeci (2008) were compared with Hanand Petyt (1996) and Chowet *al.*(1992) for the first 14 vibration modes. Similar results were obtained. [K] and [M] matrices of Morgüland Küçükrendeci (2008) were selected for the next stages of this study.

$$D_0 = E_1 h^3 / 12(1 - \nu_{12} \nu_{21})$$

$$\lambda = \rho h \omega^4 a^4 / D_0 \tag{14}$$

Linear and nonlinear frequency parameters are calculated using Eq. (14). In calculations are considered physical properties of composite plates given in section 4. The classical finite element method is used in the analyzes. New matrix of $[K]_e$ and $[K]_{eNL}$ are calculated using Eq. (4). The effect of temperature is also taken into account in these calculations. The results of the frequency values for the first 18 mode are graphically presented in Fig. 3-10. In analyzes the geometrical nonlinearity is used. In calculations is used a specially prepared computer codes in the Matlab software.

In Fig. 3, the first 15 mode frequencies are close to each other at all temperatures. At 20° C and 200° C,

frequency values are close to each other in all modes. At 240° C and 600° C, frequency values are very close to each other in all modes.

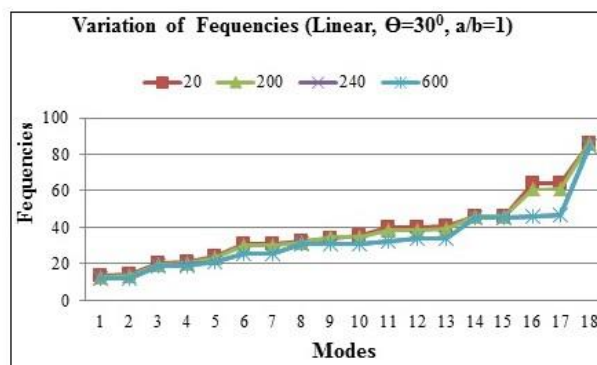

Figure 3. Linear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=30^\circ$, graphite/epoxy, $a/b=1$, temperatures; 20°C, 200°C, 240°C, 600°C)

In Fig. 4, at 200°C and 240°C temperatures, frequency values are similar in all modes. Low frequencies are observed at the temperature of 600°C. At 20°C temperature, a rise in frequency is seen after the tenth mode. In Fig. 5, at 20° C, 200°C and 600°C temperatures, frequency values are similar in all modes. At temperature of 240°C, frequency values are getting lower after the tenth mode. In Fig. 6, at 600°C, frequency values are higher in all modes. At temperatures of 200°C and 240°C, frequencies are close to each other in all modes. In 20°C temperature, frequency values are variable.

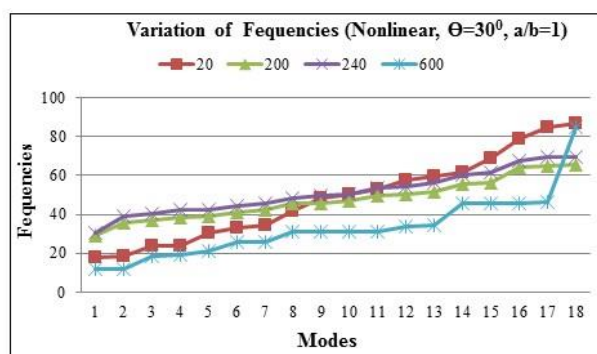

Figure 4. Nonlinear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=30^\circ$, graphite/epoxy, $a/b=1$, temperatures; 20°C, 200°C, 240°C, 600°C)

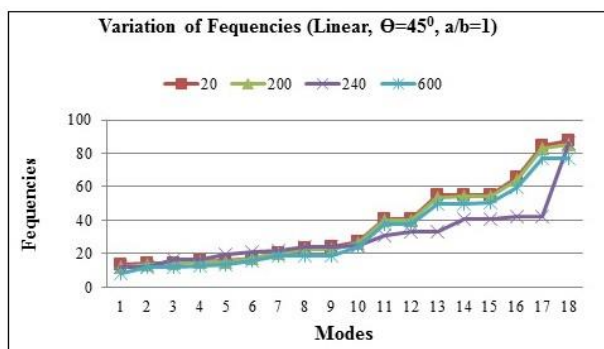

Figure 5. Linear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=45^\circ$, graphite/epoxy, $a/b=1$, temperatures; 20°C , 200°C , 240°C , 600°C)

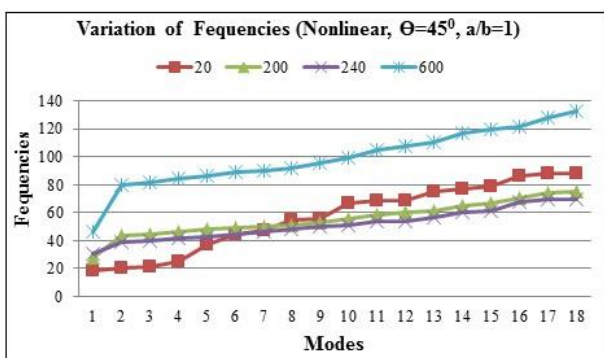

Figure 6. Nonlinear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=45^\circ$, graphite/epoxy, $a/b=1$, temperatures; 20°C , 200°C , 240°C , 600°C)

In Fig. 7, at 20°C , 200°C , 240°C and 600°C temperatures, frequency values are similar in the first twelve modes. So it can be said that there is no significant effect of temperature for these modes.

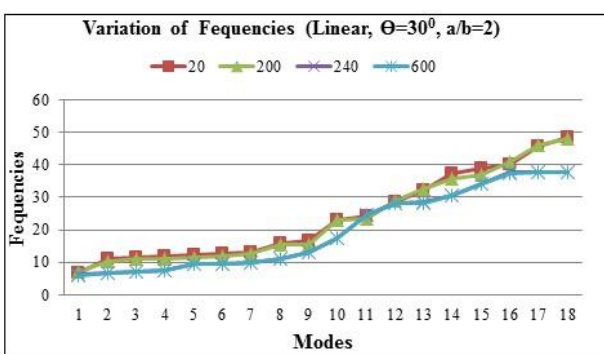

Figure 7. Linear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=30^\circ$, graphite/epoxy, $a/b=2$, temperatures; 20°C , 200°C , 240°C , 600°C)

In Fig. 8, at temperature of 600°C , frequency values are high in all modes. At temperatures of 200°C

and 240°C , frequencies are close to each other in all modes. At 20°C , 200°C and 240°C temperature, after the tenth mode, frequency values are close to each other.

Figure 8. Nonlinear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=30^\circ$, graphite/epoxy, $a/b=2$, temperatures; 20°C , 200°C , 240°C , 600°C)

In Fig. 9, at 20°C , 200°C , 240°C and 600°C temperatures, frequency values are similar in all modes. In these conditions can be said that there is no significant effect of temperature. In Fig. 10, at a temperature of 600°C , frequency values are high in all modes. At the temperature of 20°C , frequencies have the lowest value in all modes. At temperatures of 200°C and 240°C , frequencies are close to each other in all modes.

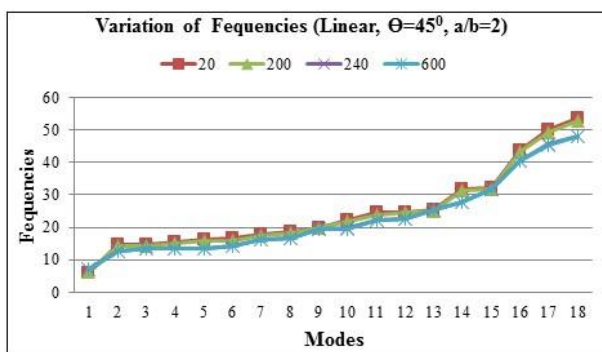

Figure 9. Linear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=45^\circ$, graphite/epoxy, $a/b=2$, temperatures; 20°C , 200°C , 240°C , 600°C)

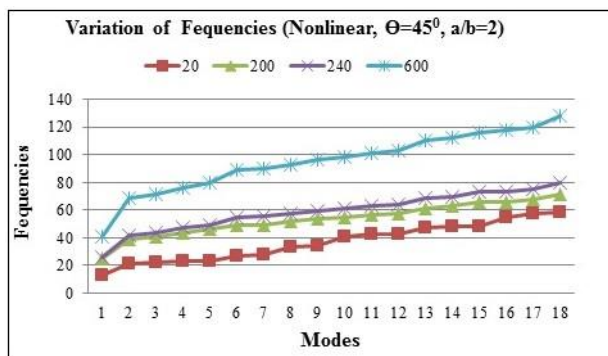

Figure 10. Nonlinear frequency parameters of laminated composite plate model supported by springs at fully clamped boundary conditions ($\theta=45^\circ$, graphite/epoxy, $a/b=2$, temperatures; 20°C , 200°C , 240°C , 600°C)

6. Conclusions

Nonlinear vibrations analyzes of composite plates on elastic foundations in thermal environments have been presented using classical finite element method. Numerical calculations have been made for symmetric composite plates exposed to high temperatures. The numerical results reveal that foundation stiffness, orientation angle of laminates and temperature rise have significant effects on the natural frequencies of composite plates. Also, dimensions of composite plates have a significant effect on the natural frequencies. Linear and nonlinear vibration analyzes are very important in applications of composite plates. Nonlinear analyzes may help to prevent some negatives situations in the applications of composite plates.
