

Orijinal araştırma (Original article)

Insect fauna of Kovada Lake National Park Basin (Isparta, Turkey)¹

Kovada Gölü Milli Parkı (İsparta, Türkiye) Havzasının böcek faunası

Baran ASLAN^{2*}

İsmail KARACA³

Summary

The study was conducted to determine insect fauna of Kovada Lake National Park Basin in Isparta province of Turkey between April 2007 and October 2008. In the study, various collecting methods, including pitfall trap, sweeping, air-sweepnet, drop sheet and light trap were used in nine different habitats selected from the region. The insect specimens were collected by weekly samplings. A total of 240 insect species and subspecies belonging to 75 families and 11 orders were recorded from the national park basin.

Key words: Insect, fauna, sampling methods, Kovada Lake, Turkey

Özet

Çalışma, Isparta ili sınırları içerisinde yer alan Kovada Gölü Milli Parkı Havzası böcek faunasının belirlenmesi amacıyla Nisan 2007-Ekim 2008 tarihleri arasında yürütülmüştür. Çalışma kapsamında, alandan seçilen farklı özellikteki dokuz habitatta çukur tuzak, süpürme, hava atrabı, Japon şemsiyesi ve ışık tuzağı yöntemleri kullanılmıştır. Örnekler, haftalık periyotlar şeklinde düzenli örneklemelerle toplanmıştır. Sonuç olarak, milli park havzasında 11 takıma bağlı, 75 familyadan 240 böcek tür ve alttürü saptanmıştır.

Anahtar sözcükler: Böcek, fauna, örneklemeye yöntemleri, Kovada Gölü, Türkiye

Introduction

Insects are the largest group in the world in terms of diversity. They live in every region of the earth and comprise a very large group of the food chain, providing the mechanism that allows the balance of nature. The number of species living on Earth is approximately 1,300,000 (Mora et al., 2011) and most of them are insects (Trautwein et al., 2012).

Turkey is located at the crossroads of three continents and has an extremely important position for biological diversity in the world. The Conservation International (CI) organization identified 34 hotspots around the world that are specific areas of the Earth's land surface that have a disproportionately large number of extant species (Myers, 2001). The Mediterranean basin, including Turkey's western and southern coastlines, is one of those hotspots (Myers et al., 2000).

The selected study area, Kovada Lake, is located within the boundaries of the city of Isparta in southern Turkey. Since 1970 it has had the status of National Park. The National Park concept includes scientific and aesthetic values, national and international protection of rare natural and cultural resource values, recreation and tourism areas of the nature. The study area was defined as a first level protected area in 1992, covering an area of 6534 hectares with its surroundings. The Lake has karstic morphology and a total area of about 790 ha. The National Park has 259 genera and 361 species of plants belonging to 75 families of which 28 species are endemic (Bayram, 2007). In the study area, 153 waterfowl species were recorded, including wild duck, goose, shelduck, partridge and woodcocks (Anonymous, 2003). It is an internationally important wetland and is also used for drinking water, irrigation, aquaculture, fisheries, hydropower and recreation (Anonymous, 2004).

Although many studies on many topics have been conducted on Kovada Lake, there have been no studies conducted on the insect fauna. Therefore, the aim of this study was to determine the insect fauna of the Kovada Lake Natural Park Basin. The study was a preliminary step in determining the insect families, genera and species. Obviously, the number of the species found in this study may be increased considerably by more specific studies focusing on small groups.

Material and Methods

Study sites

Studies were carried out from April 2007 to October 2008 in Kovada Lake National Park (Figure 1.). The study area was divided into nine different sampling sites because of different plant associations. Aquatic and semi aquatic habitats were ignored within the scope of the study. Details of habitats, including altitude, size and vegetation types, are as follows:

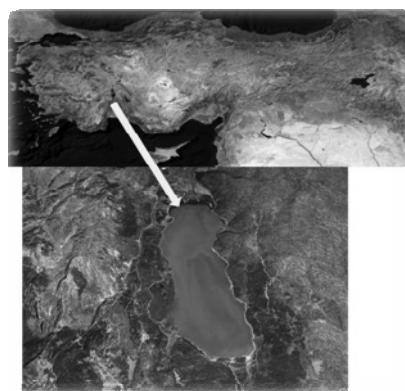

Figure 1. Location of Kovada Lake National Park Basin (Turkey).

Sand Rest Habitat: This is the closest area to the lake. The size of the area is 0.28 ha at an altitude of 927 m. It has rather scarce vegetation, including *Verbascum* spp. and *Platanus orientalis* L. trees commonly.

Maquis and Forest Habitat: The habitat includes a dry stream bed with an altitude of 943 m and 0.294 ha size. *Juniperus oxycedrus* L., *Thuja orientalis* L., *Crataegus monogyna* Jacq, *Cistus ladaniferus* Weisse, *Pistacia lentiscus* L., *Rosa canina* L. and *Platanus orientalis* L. comprise the dominant vegetation of the area.

Meadow Area Habitat: The area is located in the south part of the Kovada Lake at 941 m altitude and is 0.275 ha. Unlike other habitats, it has only annual herbaceous vegetation. *Echium italicum* L., *Glaucium corniculatum* ssp. *corniculatum* (L.), *Trifolium resupinatum* L. var. *resupinatum*, *Anthemis arvensis* L., *Leontodon tuberosus* L., *Achillea multifida* Boiss. and *Cardaria draba* (L.) are the most common plant species.

Mixed Forest Habitat: This habitat was selected from a forest area at 974 m altitude, with a land area of 0.265 ha. *Quercus robur* L. and *Pinus nigra* Arnold are the most common plant species and are mixed with some annual plants like *Ornithogalum oligophyllum* Clarke and *Cyclamen cilicum* Boissier & Heldreich.

Forest Coast Habitat: It includes a land area of 0.278 ha at an altitude of 929 m. The dominant plant species are *Pistacia lentiscus* L., *Q. robur*, *Q. coccifera* and *Carduus rechingeranus* Kazmi.

Open Area Habitat: The area is like a plain dried from the lake. *C. draba* and *A. multifida* are the common species of the vegetation, accompanied by some annual plants.

Fruit Plantation Habitat: The habitat has an altitude of 919 m covering about 0.308 ha land area. An apple orchard is the dominant vegetation together with some other vegetable crops. Shrubs were removed from the area in order to grow apples.

Maquis Coast Habitat: *Platanus orientalis* L. represents the dominant vegetation of the area. The approximate altitude is 911 m and size 0.184 ha. *Xanthium strumarium* L. and some members of the plant family Poaceae were other species observed in the area.

Maquis Habitat: Unlike the other two habitats including maquis, the area has only scrubs. It is at 911 m altitude and is 0.082 ha. Vegetation mainly includes *Pistacia lentiscus* L., *J. oxycedrus*, *Thuja orientalis* L., *C. monogyna*, *C. ladaniferus*, *Q. coccifera* and *R. canina*.

Sampling methods

Studies were carried out from April 2007 to October 2008 in the Kovada Lake National Park Basin, divided into three different main areas and nine sub-areas. Insect samples were collected using pitfall trap, light trap, sweepnet, sweeping and drop sheet weekly. The methods are briefly described below.

Pitfall trap method: In all sampling areas, 10 pitfall traps (15 cm depth and 17 cm diameter) were established at 25 meters intervals. They were carefully maintained in order to keep top of the cup and surface of the ground at the same level. Traps were checked weekly and the trapped insects were collected into the killing bottles. Samples were mounted in the laboratory and identified to family.

Sweeping method: This method was used to capture insects on short plants and herbaceous vegetation, and was used in all habitats except the Mixed Forest Habitat. Samplings were carried out using a 35 cm diameter sweepnet, and an aspirator for sucking small insects, if necessary. Sweep netting included 200 sweeps in each habitat. After every 20 sweeps, insects in the sweepnet were transferred to the killing bottles. At the end of sweeping, the entire mass was transferred to separate plastic bottles and brought to the laboratory for pinning and labeling.

Air-sweepnet method: This method was used to capture flying insect groups. An air-sweepnet, made with light fabric through which air can flow freely and of 30 cm diameter and 90 cm depth was used for a 20 minutes period per week in all habitats.

Drop sheet method: This method was applied in order to capture insects on the branches of shrubs or trees. An ordinary white-colored umbrella was used as a beating sheet. The umbrella was inverted under the branches of trees or shrubs, and the branches sharply beaten with a stick for detaching the insects that shelter in vegetation. The method was used only in Maquis and Forest, Mixed Forest, Fruit Plantation, Maquis Coast and Maquis habitats and was applied ten times for each plant.

Light trap method: The method was used for the sampling of night active insects. A mercury vapor lamp reflected from white cloths of 180x220 cm. The generator was started at sunset and sampling continued until midnight. Attracted insects were collected and transferred to the killing bottles. This method was applied once in each of the three main areas during the first year and a total of six times in the two year study.

Sampling methods and habitats are shown in Table 1. All the collected insect specimens are deposited in the EMIT (Entomological Museum of Isparta, Turkey) at Suleyman Demirel University.

Table 1. Sampling methods and habitats in Kovada Lake National Park Basin

Habitats	Sampling Methods

Open Area Habitat	+	+	+		
Fruit Plantation Habitat	+	+	+	+	
Maquis Coast Habitat	+	+	+	+	+
Maquis Habitat	+	+	+	+	

Results and Discussion

A total of 240 insect taxa belonging to 75 families and 11 orders were collected in surveys conducted in 9 different habitats of Kovada Lake National Park basin. Among the samples, 36 taxa were identified to genus level, 10 were identified to family level, and the remainder were identified to species level. Species are listed alphabetically in Table 2 with habitat information, sampling year and abundance data. The numbers of individuals and species collected in 2008 (10,601 individuals belonging to 201 species) were higher than those collected in 2007 (6,652 individuals belonging to 186 species).

** M.s.: Morpho species.

Coleoptera (44%) was the most frequently sampled order with 22 families and 106 species, followed by Hemiptera (16%), Hymenoptera (12%) and Lepidoptera (10%). Species richness of the Carabidae (24), Chrysomelidae (21), Acrididae (14) and Nymphalidae (9) families was higher than that of other families. Distributions of the number of species and families among the 11 collected insect orders are given in Figure 2.

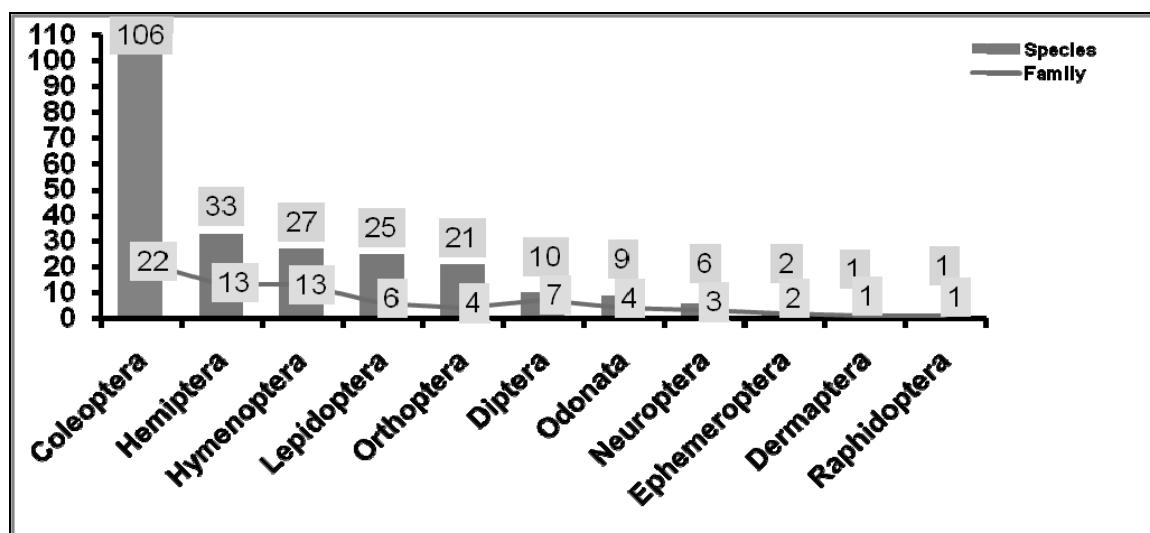

Figure 2. Number of species and families belonging to the twelve orders recorded in Kovada Lake National Park Basin in 2007-2008.

An unidentified species belonging to the family Chironomidae (Diptera) was the most dominant species among all others with a huge individual number. For that reason, it was not included in any further numerical calculations. Apart from it, the most common species were *Daiognatha quadricollis* Brullé (Coleoptera: Tenebrionidae) (10.97%), *Calathus longicollis* Motschulsky (Coleoptera: Carabidae) (1.96%), *Pedinus fallax* Mulsant&Rey (1.74%) (Coleoptera: Tenebrionidae), *Mylabris quadripunctata* (L.) (Coleoptera: Meloidae) (1.61%) and *Camponotus turkestanus* Andrè (Hymenoptera: Formicidae) (1.59%), respectively. *Ischyroptyx* sp. (Hymenoptera: Pteromalidae) (0.01%), *Prosopis* sp. (Hymenoptera: Colletidae) (0.01%) and *Palpares libelluloides* (Linnaeus) (Neuroptera: Myrmeleontidae) (0.02%) were the rarest species. *D. quadricollis* (Coleoptera: Tenebrionidae) was collected in both study years and in all habitats.

The Open Area Habitat was the most diverse area in terms of sampled species and individual numbers. It seems that the most important reason for this result was the collecting method, as with the sweeping method a large number of individuals and species can be collected (Zubareva, 1930). The Open Area Habitat's annual herbaceous diversity supported an abundance of different species.

The Open Area Habitat was closely followed by Forest Coast Habitat. The presence of trees in that habitat, as well as herbaceous plants and perennial plants, positively affected the species composition. However, the Mixed Forest Habitat was the least diverse area, based on number of species and individuals. The possible reason for this is the less diverse and uniform composition of plant species. Similar results were obtained for the Sand Rest Habitat.

Carabidae (24) and Tenebrionidae (9) were the most species-rich families. Carabidae and Tenebrionidae species are usually adapted to the arid areas more than herbaceous lands. Especially, Carabidae species can survive in very different biotypes (Lovei & Sunderland, 1996; Mercan et al., 2004). The presence of individuals belonging to both families in nearly all selected habitats in Kovada Lake National Park supports that contention. Among the sampled species, *D. quadricollis* (10.97%) was the most common. This tenebrionid species is known to have a wide distribution (Tezcan et al., 2004). In a similar study conducted in Kasnak Meşesi Nature Reserve, very close to the study area, *D. quadricollis* was also reported as the most common species (Aslan et al., 2008).

Compared with previous studies conducted in different protected areas, in terms of sampled number of species and individuals, Kovada Lake National Park Basin's insect fauna appears to be poor. Factors such as the park area being open to visitors, illegal hunting, livestock grazing and the contamination of the lake by irrigation water may be responsible. Agricultural activities such as fertilizing and spraying in the surroundings and orchards within the boundaries of the National Park probably also negatively affect the fauna. Reduction or elimination of all of these negative human impacts may positively affect the fauna and also diversity of the Kovada Natural Park.

Turkey is one of the important regions of the world in terms of biological diversity. Approximately 19% of its land area is recognized as important natural areas, although only 20% of these areas are protected (Anonymous, 2008). Kovada Lake itself is recognized one of the most important fresh water resources in Turkey and worldwide.

Increasing the protection of this important natural area, preventing irrigation water from contaminating the lake and closure of the surrounding orchards and gardens would positively affect the diversity of the Natural Park. Similar studies to the present one conducted in different protected areas would help to understand the actual diversity of these lands, and contribute to the protection of Turkey's biological diversity.

This study is a preliminary step in the description of the insect fauna of Kovada Lake National Park Basin and can be used as a reference study for similar faunistic studies in the future.

Acknowledgements

We are grateful to: Dr. Esat PEHLİVAN (Ege University, Faculty of Agriculture, Department of Plant Protection, İzmir, Turkey) for determining Geotrophidae, Lucanidae and Cetoniidae (Coleoptera) specimens, Dr. Rüstem HAYAT (Süleyman Demirel University, Faculty of Agriculture, Department of Plant Protection, Isparta, Turkey) for determining Tabanidae (Diptera) samples, Dr. Ali DEMİRSOY (Hacettepe University, Faculty of Science, Department of Biology,, Ankara, Turkey) for determining Odonata samples, Dr. Battal ÇIPLAK (Akdeniz University, Faculty of Science, Department of Biology, Antalya, Turkey) for determining Orthoptera specimens, Dr. Hüseyin BAŞPINAR (Adnan Menderes University, Faculty of Agriculture, Department of Plant Protection, Aydın, Turkey) for determining Cicadellidae, Cicadidae (Hemiptera) specimens, Dr. Coşkun GÜÇLÜ (Atatürk University, Faculty of Agriculture, Department of Plant Protection, Erzurum, Turkey) for determining Braconidae (Hymenoptera) samples, Dr. Erol YILDIRIM (Atatürk University, Faculty of Agriculture, Department of Plant Protection, Erzurum, Turkey) for determining Vespidae (Hymenoptera) samples, Dr. Göksel TOZLU (Atatürk University, Faculty of Agriculture, Department of Plant Protection, Erzurum, Turkey) for determining Buprestidae (Coleoptera) samples, Dr. Mustafa AVCI (Süleyman Demirel University, Faculty of Forestry, Department of Forest Protection, Isparta, Turkey) for determining Lepidoptera samples, Dr. Ebru GüL ASLAN (Süleyman Demirel University, Faculty of Sciences and Arts, Department of Biology, Isparta, Turkey) for determining Alticinae (Coleoptera: Chrysomelidae) samples, Dr. Ali GÖK (Süleyman Demirel University, Faculty of Sciences and Arts, Department of Biology, Isparta, Turkey) for determining Chrysomelidae (Coleoptera) samples, Dr. Kenan KARA (Gaziosmanpaşa University, Faculty of Agriculture, Department of Plant Protection, Tokat, Turkey) for determining Tachinidae (Diptera) specimens, Dr. George JAPOSHVILI (Illa Chavhavadze State University, Institute of Zoology, Department of Entomology, Tiflis, Georgia) for determining Formicidae (Hymenoptera) specimens, Dr. Meral FENT (Trakya University, Faculty of Science and Arts, Department of Biology, Edirne, Turkey) for determining Alydidae, Coreidae, Lygaeidae, Miridae, Notonectidae,

Pentatomidae, Rhopalidae, Scutelleridae, Stenocephalidae (Hemiptera) samples, Dr. Savaş CANBULAT (Sakarya University, Faculty of Sciences and Arts, Department of Biology, Sakarya, Turkey) for determining Neuroptera and Raphidioptera samples, Dr. Hasan KOÇ (Muğla University, Faculty of Sciences and Arts, Department of Biology, Muğla, Turkey) for determining Tipulidae (Diptera) samples, Dr. Levent GÜLTEKİN (Atatürk University, Faculty of Agriculture, Department of Plant Protection, Erzurum, Turkey) for determining Curculionidae (Coleoptera) samples, Dr. Hüseyin ÖZDİKMEN (Gazi University, Faculty of Science and Arts, Department of Biology, Ankara, Turkey) for determining Cerambycidae (Coleoptera) samples, Dr. Memiş KESDEK (Mugla University, Fethiye Ali Sitki Mehfaret Kocman Vocational School, Muğla, Turkey) for determining Carabidae (Coleoptera) specimens, Dr. Üzeyir ÇAĞLAR (Ahi Evran University, Faculty of Education, Department of Science Education, Kırşehir, Turkey) for determining Meloidae and Elateridae (Coleoptera) samples, Dr. Toshko LJUBOMIROV (Plovdiv University, Faculty of Pedagogie, Plovdiv, Bulgaria) for determining Sphecidae (Hymenoptera) specimens, Dr. Derya CANPOLAT (Gazi University, Faculty of Science and Arts, Department of Biology, Ankara, Turkey) for determining Tenebrionidae (Coleoptera) specimens and Giorgi CHALADZE (Illa Chavhavadze State University, Institute of Zoology, Department of Entomology, Tbilisi, Georgia) for determining Scarabeidae (Coleoptera) samples.

We would also like to thank the Department of Scientific Research Project Management of Süleyman Demirel University in Isparta, Turkey for supporting this study (Project number 1421-D-07).
