#### Abstract

Gibbs free energy and acidic dissociation constants are two important thermodynamic properties of molecules. A combination of ab initio with the density functional theory (DFT) and the polarized continuum model (PCM) of Tomasi's method were utilized to calculate the acidic dissociation constants of arginine and glutamic acid in water. We applied the basis set at the B3LYP/6-31+G(d) level of theory for accurate theoretical predictions of $\mathrm{pK}_{\mathrm{a}}$ values. Furthermore, we have evaluated the molecular conformations and solute-solvent interactions of these molecules by the electronic structure theory (commonly DFT method). It was found that in alkaline aqueous solutions the cation, anion, and neutral species of arginine and glutamic acid are solvated with one, two, three, and four molecules of water, respectively. There are intermolecular hydrogen bonds between the existent species and water molecules. The atomic charges were investigated to analyze the reaction mechanism. In this study, it can be seen that there is a good correlation between experimental attained $p K_{a}$ values and the theoretical computed $\mathrm{pK}_{\mathrm{a}}$ values.

## Key Words

Arginine, Glutamic Acid, DFT Method, Acidic Dissociation Constant.

## ÖZET

#### Abstract

ibbs serbest enerji ve asidik ayrışma sabiti, moleküllerin iki önemli termodinamik özellliğidir. Ab initio'nun yoğunluk fonksiyonel teori (DFT) ile kombinasyonu ve Tomasi'nin polarize olmuş sürekli dizi modelinden (PCM) yararlanılarak sudaki arjinin ve glutamik asitin asidik ayrışma sabitleri hesaplanmıştır. pK değerinin teorik tahmini için B3LYP/6-31+G(d) teori seviyesi uygulaması kullanılmıştır. Ayrıca elektronik yapı teorisiyle (geleneksel DFT yöntemi) bu moleküllerin moleküler konformasyonları ve çözünen-çözücü etkileşimleri incelenmiştir. Elde edilen bulgulara gore alkali sulu çözeltilerde arjinin ve glutamik asitin katyon, anyon ve nötral türleri, sırasıyla, bir, iki, üç ve dört su molekülü ile çözünmüştür. Varolan türler ile su molekülleri arasında molekül içi hidrojen bağları vardır. Tepkime mekanizmasını analiz etmek için atomik değişimler araştırılmıştır. Bu çalışmada, deneysel $\mathrm{pK}_{\mathrm{a}}$ değerleri ile teorik $\mathrm{pK}_{\mathrm{a}}$ değerleri arasında iyi bir ilişki olduğu görülmektedir.

## Anahtar Kelimeler

Arjinin, Glutamik asit, DFT yöntemi, Asidik ayrışma sabiti.

## INTRODUCTION

Proteins are the primary structural and functional polymers in living systems [1]. They have a broad range of activities, including catalysis of metabolic reactions and transport of vitamins, minerals, oxygen, and fuels. Some proteins make up the structure of tissues [2-4] while others function in nerve transmission $[5,6]$, muscle contraction and cell motility, and still others in blood clotting and immunologic defenses, and as hormones and regulatory molecules [7,8]. Proteins are synthesized as a sequence of amino acids connected together in a linear polyamide (polypeptide) structure. There are near 300 amino acids present in various animal, plant and microbial systems, but only 20 amino acids are coded by DNA to appear in proteins, such as arginine and glutamic acid [9]. These molecules are -amino acid. It means that the -carbon atom has a - COOH group, an $-\mathrm{NH}_{2}$ group, and an ' R '-group which is responsible for the different properties of the different amino acids. Arginine and glutamic acid are classified as basic amino acids and acidic amino acids, respectively [10]. Glutamic acid contains carboxylic acid on its sidechain and is ionized at $\mathrm{pH}=7.0$. Thus, it can be carried negative charges on its -carboxyl group. In the ionized state, this amino acid is referred to as glutamate. The side-chain of arginine is fully protonated at neutral pH and therefore, positively charged. Arginine is the most basic amino acid $\left(\mathrm{pK}_{\mathrm{a}}=13\right)$ and its guanidine group exists as a protonated guanidinium ion at $\mathrm{pH}=7.0$ [11].

Acid equilibrium constant $\left(\mathrm{K}_{\mathrm{a}}, \mathrm{pK}_{\mathrm{a}}=-\log \mathrm{K}_{\mathrm{a}}\right)$ is an important property of organic compounds, with extensive effects on several biological and chemical systems. Aqueous $\mathrm{pK}_{\mathrm{a}}$ values are especially useful because of their environmental and pharmacological usages $[12,13]$.
$\mathrm{pK}_{\mathrm{a}}$ values are related to a number of properties of drugs such as solubility, extent of binding, and rate of absorption. In addition, the determination of dosage forms and the regimes of drugs are also related to their $\mathrm{pK}_{\mathrm{a}}$ values [14]. A number of methods (both experimental and theoretical) have been employed to calculate $\mathrm{pK}_{\mathrm{a}}$ values [15-19]. Experimentally determined $\mathrm{pK}_{\mathrm{a}}$ values are not always available from literature
sources and often estimated values are employed in their place. Therefore, there is a high interest to expand methods for estimating $\mathrm{pK}_{\mathrm{a}}$ of ionizable compounds and use these methods to predict the properties of a chemical in an aqueous environment [17-19]. Experimental determination of individual $\mathrm{pK}_{\mathrm{a}}$ values can be quite complicated in complex systems such as proteins, or inhibitorenzyme complexes. In principle, quantum chemical methods can provide a reliable and accurate means of calculating relative and (or) absolute $\mathrm{pK}_{\mathrm{a}}$ values [20]. Theoretically, it is possible to calculate dissociation constants from first principles using quantum mechanical methods. In order to obtain accurate enough energies to calculate solution phase dissociation constants, one must account for electron correlation at the ab initio or density functional theory (DFT) and consider the effects of solvation on the molecule. In this method, electronic structure calculations were performed with density functional theory and the electrostatic features were modeled through external charge distributions and continuum dielectrics. The correlation of theoretical and experimental data can allow the development of predictive models to determine the $\mathrm{pK}_{\mathrm{a}}$ of compounds for which no experimental data are yet available. The theoretical determination of aqueous $\mathrm{pK}_{\mathrm{a}}$ values remains a challenging problem for computational chemists. The ab initio calculation of $\mathrm{pK}_{\mathrm{a}}$ values in solvents (other than water) is easily achieved using continuum solvation models. Water is a very challenging solvent to model because of the large amount of hydrogen bonding that is not considered in continuum solvation models. However, such values are problematic, since the acidity of water does not allow direct equilibrium measurements of organic acids with $\mathrm{pK}_{\mathrm{a}}$ values above the $\mathrm{pK}_{\mathrm{a}}$ of water (15/7). The acid-base equilibria of biological important molecules are often difficult to study experimentally, particularly when the molecule contains some ionisable groups or when the $\mathrm{pK}_{\mathrm{a}}$ of a given group is close to that of the solvent [21]. Also, potentiometric determination of accurate $\mathrm{pK}_{\mathrm{a}}$ values below 1.5 is difficult [22].

Our purpose is to calculate the acidic dissociation constants of arginine and glutamic acid in aqueous solution by ab initio method
at $\mathrm{T}=298.15 \mathrm{~K}$. To explain the obtained acidic dissociation constants, we investigated the molecular conformations (Figure 1) and solutesolvent interactions of amino acids by the electronic structure theory, (mainly) density functional theory (DFT), and self-Consistent Reaction Field (SCRF) model.

Figure 1. Optimized structure of glutamic acid and arginine for performing the calculations.

## COMPUTATIONAL METHOD

The optimized structures of all species of glutamic acid and arginine were carried out using DFT and ab initio methods. All the initial geometries and solvated molecules (in water) were optimized considering the intermolecular hydrogen bonds of water with amino and carboxyl groups with the Gaussian 09 program packages using hybrid density functional B3LYP [23], the Becke's threeparameter exchange functional, and the Lee-Yang-Parr correlation functional $[24,25]$ using $6-31+G(d)$ basis function. All of species include cation $\left(\mathrm{H}_{3} \mathrm{~L}^{+}\right)$, natural $\left(\mathrm{H}_{2} \mathrm{~L}\right)$, single negative charge anion $\left(\mathrm{HL}^{-}\right)$and double negative charge anion ( $\mathrm{L}^{2-}$ ) for glutamic acid and double negative charge cation $\left(\mathrm{H}_{3} \mathrm{~L}^{2+}\right)$, single negative charge cation $\left(\mathrm{H}_{2} \mathrm{~L}^{+}\right)$, natural $(\mathrm{HL})$ and anion ( $\mathrm{L}^{-}$) for arginine and also, their $n$-hydrated $\left(\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{n}, \mathrm{n}=1-4\right)$ structures have been optimized at the B3LYP/6-31+G(d) level of theory. The single-point calculations at the same level of theory have been employed for solvent-effect interactions using the polarizable continuum model (PCM) of Tomasi and coworkers in the Self-Consistent Reaction Field (SCRF) model [26].

Finally, we selected the solvation of the species by means of intermolecular hydrogen bonds (IHBs) that involve one molecule of the mentioned species and some molecules of water (see Table 1).

## RESULTS

For an acidic compound, the value of $\mathrm{pK}_{\mathrm{a}}$ can be calculated by the following equation [27]:
$p K_{a}=-1 / 2.303 R T \Delta G_{0}$
Where $R$ is the gas constant, $T$ is the temperature, and $\Delta G_{0}$ is the free energy change of the dissociation reaction either in a gas or solution. The total energies of the single and solvated (in water) glutamic acid and arginine structures (cationic, natural and anionic) were calculated at the B3LYP/6-31+G(d) level of the theory, applying Tomasi's method (see Table 1).

Glutamic acid and arginine have hydrogen atoms which can contribute in interaction with the solvent molecules (water). In other words, these molecules can be ionized. Glutamic acid molecule has two carboxyl groups and one amino group while, arginine molecule has one carboxyl group and two amino groups. Therefore, these molecules have three acidic dissociation constants. It seems reasonable that at first, carboxyl and then amino group is deprotonated. We represent $\mathrm{H}_{3} \mathrm{~L}^{+}, \mathrm{H}_{2} \mathrm{~L}, \mathrm{HL}$, and $L_{2}$ for cationic, neutral and anionic structures of glutamic acid and also, $\mathrm{H}_{3} \mathrm{~L}^{+2}, \mathrm{H}_{2} \mathrm{~L}^{+}, \mathrm{HL}$, and $\mathrm{L}^{-}$of arginine, respectively.

## DISCUSSION

## First ionization constant of glutamic acid and arginine:

The following equations were chosen for the first ionization constant of glutamic acid and arginine:
$\mathrm{H}_{3} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)+\mathrm{OH}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right) \leftrightarrow \mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+\mathrm{H}_{2} \mathrm{O} \mathrm{K}_{\mathrm{C} 1 \mathrm{G}}$
$\mathrm{H}_{3} \mathrm{~L}^{+} 2\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+\mathrm{OH}^{-} \leftrightarrow \mathrm{H}_{2} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)+2 \mathrm{H}_{2} \mathrm{O} \quad \mathrm{K}_{\mathrm{c} 1 \mathrm{~A}}$

Reaction 2 is partial neutralization in alkaline glutamic acid. In this reaction, $\mathrm{H}_{3} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)$ is the glutamic acid cation solvated with one water molecule (Figure 2) and $\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ is the neutral glutamic acid solvated with two water molecules (Figure 3). In reaction $3, \mathrm{H}_{3} \mathrm{~L}^{2+}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ (Figure 2) and $\mathrm{H}_{2} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)$ are the arginine cations solvated by two and one water molecule, respectively (Figure 4). These reactions are characterized by

Table 1. Calculated total energy using the Tomasi's method at the B3LYP/6-31+G(d) level of theory for cationic, neutral, and anionic species of glutamic acid and arginine at 298.15 Ka .

Figure 2. Optimized structure of glutamic acid and arginine cations solvated with one and two molecules of water, respectively and practical numbering system accepted for performing the calculation.

$\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$
Figure 3. Optimized structure of neutral glutamic acid solvated with two molecules of water and practical numbering system accepted for performing the calculation.

Figure 4. Optimized structure of arginine cations solvated with one and two molecules of water and practical numbering system accepted for performing the calculation.
two equilibrium constants ( $\mathrm{K}_{\mathrm{C} 16}$ and $\mathrm{K}_{\mathrm{C} 1 A}$ ) which were theoretically calculated. Moreover, water autopyrolysis occurs according to the following equations:

$$
\begin{array}{ll}
3 \mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right) & \mathrm{K}_{\mathrm{w}} \\
2 \mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} & \mathrm{K}_{\mathrm{N}} \tag{5}
\end{array}
$$

By merging Equations 2 and 4 for glutamic acid and also, 3 and 4 for arginine, we can obtain the Equations 6 and 7, which describe the first ionization constants of glutamic acid ( $\mathrm{K}_{\text {alc }}$ ) and arginine ( $\mathrm{K}_{\mathrm{a} 1 \mathrm{~A}}$ ):
$\begin{array}{ll}\mathrm{H}_{3} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)+2 \mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+\mathrm{H}_{3} \mathrm{O}^{+} & \mathrm{K}_{\mathrm{a} 1 \mathrm{G}} \\ \mathrm{H}_{3} \mathrm{~L}+2\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \leftrightarrow \mathrm{H}_{2} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)+\mathrm{H}_{3} \mathrm{O}^{+}\end{array} \quad \mathrm{K}_{\mathrm{atA}}$ (7)
It is obvious that the constants $\mathrm{K}_{{\mathrm{c} 1 G^{\prime}}} \mathrm{K}_{\mathrm{w}^{\prime}}$ and $\mathrm{K}_{\mathrm{a} 1 G}$ are related by:
$K_{\mathrm{a} 1 G}=\mathrm{K}_{\mathrm{c} 1 G} \cdot \mathrm{~K}_{\mathrm{w}}$
Also $\mathrm{K}_{\mathrm{ClA}^{\prime}} \mathrm{K}_{\mathrm{N}^{\prime}}$ and $\mathrm{K}_{\mathrm{a} 1 \mathrm{~A}}$ make following equation:
$K_{\mathrm{a} 1 \mathrm{~A}}=\mathrm{K}_{\mathrm{ClA}} \cdot \mathrm{K}_{\mathrm{N}}$

The Equations 8 and 9 were applied to theoretical calculate the value of the first ionization constants of glutamic acid and arginine in water. Table 2 resumes the optimized values of molecular properties of the $\mathrm{H}_{3} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)$ cation and $\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ neutral molecule (Figures 2 and 3 ), obtained at the B3LYP/6-31+G(d) level of theory with Tomasi's method in water at $\mathrm{T}=298.15 \mathrm{~K}$.

We have obtained the atomic charges (which are listed in Table 2) to describe the mechanism of reaction 2 . This table shows that the negative atomic charge of $\mathrm{O}_{7}\left(\mathrm{qO}_{7}\right)$ of the neutral glutamic acid increases (in absolute value). It shows that the nucleophilic attack of $\mathrm{O}^{-}$atom of the $\mathrm{OH}^{-}$ion (see Eq 2) on the $\mathrm{H}_{16}$ atom of the carboxyl group bound to $\mathrm{C}_{2}$ of the glutamic acid cation generated the neutral glutamic acid and two molecule of water (Figure 2).

In addition, in the Table 2, we are collocated the distances and angles of internal hydrogen bounds (IHBs). These values indicate that the IHB of the cation, neutral and anion of glutamic acid attach to class of weak to moderate IHBs. The properties of the moderate hydrogen bonds have the following classifications [28]: bond lengths of $\mathrm{H} \cdot \cdots \mathrm{B}$ are between ( 1.5 and 2.2) $\AA$ and the bond angle is $130^{\circ}$ to $180^{\circ}$. For weak hydrogen bonds, the bond length and angle are ( 2.2 to 3.2 ) $\AA$ and $90^{\circ}$ to $150^{\circ}$, respectively and also, for strong hydrogen bonds these amounts are (1.2 to 1.5) $\AA$ and $175^{\circ}$ to $180^{\circ}$, respectively. As it can be seen in Table 3, the comparison of theoretical $\left(\mathrm{pK}_{\mathrm{a} 1}=2.19\right)$ and experimental ( $\mathrm{pK}_{\mathrm{a}} 2=1.820$ ) values show good range located.

For first ionization constant of arginine molecule, the same calculations and ratiocinations were done. The result of these calculations was shown in the Tables 3, 4 and also, Figure 4.

## Second ionization constant of glutamic acid and arginine:

For the second ionization constant of glutamic acid, it is selected that the neutral glutamic acid solvated with two water molecules $\left(\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right)$ also, cationic arginine solvated by two water molecules $\left(\mathrm{H}_{2} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right)$ according to the following reaction:
$\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+\mathrm{OH}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right) \leftrightarrow \mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+2 \mathrm{H}_{2} \mathrm{O}$

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}+\mathrm{OH}^{-} \leftrightarrow \mathrm{HL}\left(\mathrm{H}_{2} \mathrm{O}\right)+2 \mathrm{H}_{2} \mathrm{O} \tag{c2G}
\end{equation*}
$$

In the above reactions, $\mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ (Figure 7) and $\mathrm{HL}\left(\mathrm{H}_{2} \mathrm{O}\right)$ (Figure 5) display the anionic glutamic acid and neutral arginine that solvated with two and one water molecules, respectively. Equations 9 and 10 are expressed by equilibrium constants ( $\mathrm{K}_{\mathrm{c} 2 \mathrm{G}}$ and $\mathrm{K}_{\mathrm{c} 2 \mathrm{~A}}$ ) which were theoretically calculated. The second ionization reaction of glutamic acid and arginine can be obtained by blending Equations 9 with 4 and also, equations 10 with 5:

The equilibrium constants $\mathrm{K}_{\mathrm{a} 2 \mathrm{G}}$ and $\mathrm{K}_{\mathrm{a} 2 \mathrm{~A}}$ that define the Equations 9 and 10 are linked with the constants $\mathrm{K}_{\mathrm{C} 2 \mathrm{G}}$ and $\mathrm{K}_{\mathrm{w}}$ by eq 13 , also $\mathrm{K}_{\mathrm{C} 2 \mathrm{~A}}$ and $\mathrm{K}_{\mathrm{N}}$ by Eq 14 for glutamic acid and arginine regularity:
$\begin{aligned} \mathrm{K}_{\mathrm{a} 2 \mathrm{G}} & =\mathrm{K}_{\mathrm{c} 2 \mathrm{G}} \cdot \mathrm{K}_{\mathrm{w}} \\ \mathrm{K}_{\mathrm{a} 2 \mathrm{~A}} & =\mathrm{K}_{\mathrm{c} 2 \mathrm{~A}} \cdot \mathrm{~K}_{\mathrm{N}}\end{aligned}$

Equations 13 and 14 were used to generate the values of second ionization constants of glutamic acid and arginine in water. Table 2 summarizes the determined values of the parameters and properties for the $\mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ anion (in water) at T $=298.15 \mathrm{~K}$.

Table 2. Calculated total energy using the Tomasi's method at the B3LYP/6-31+G(d) level of theory for cationic, neutral, and anionic species of glutamic acid and arginine at 298.15 K.

| glutamic acid | $\mathrm{H}_{3} \mathrm{~L}^{+}\left(\mathrm{H}_{2} \mathrm{O}\right)$ | $\mathrm{H}_{2} \mathrm{~L}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ | $\mathrm{HL} \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ | HL-( $\left.\mathrm{H}_{2} \mathrm{O}\right)$ | $\mathrm{L}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ |

$\mathrm{K}_{\mathrm{c} 1}, \mathrm{~K}_{\mathrm{c} 2}$ and $\mathrm{K}_{\mathrm{c} 3}$ equilibrium constants of equations; $\mathrm{K}_{\mathrm{a} 1}, \mathrm{~K}_{\mathrm{a} 2}$ and $\mathrm{K}_{\mathrm{a} 3}$ first, second and third acidic dissociation constant between the indicated atoms ( $A^{\circ}$ ); D, dihedral angle between the indicated atoms $\left(^{\circ}\right.$ ); aO., bohr radius ( $A^{\circ}$ ); q, total atomic charges (Muliken) (au); d, distance of the IHB between the indicated atoms ( $\mathrm{A}^{\circ}$ ) $\mathrm{A}, \mathrm{H}$-bond angle $\left({ }^{\circ}\right)$.

$\mathrm{HL}\left(\mathrm{H}_{2} \mathrm{O}\right)$
Figure 5. Optimized structure of arginine natural solvated with one molecule of water and practical numbering system accepted for performing the calculation.

$\mathbf{L}^{-}$
Figure 6. Optimized structure of arginine anion and practical numbering system accepted for performing the calculation.

$\mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$
Figure 7. Optimized structure of glutamic acid anion solvated with two molecules of water and practical numbering system accepted for performing the calculation.

For second ionization constant of arginine molecule, the same calculations and ratiocinations were done. The result of these calculations was shown in the Tables 3, 4 and also, Figures 4 and 5.

## Third ionization constant of glutamic acid and arginine:

The following equations can be chosen for the third ionization constant of glutamic acid and arginine:

$$
\begin{array}{ll}
\mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)+\mathrm{OH}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right) \leftrightarrow \mathrm{L}_{2}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3} & \mathrm{~K}_{\mathrm{c} 3 \mathrm{G}} \\
\mathrm{HL}\left(\mathrm{H}_{2} \mathrm{O}\right)+\mathrm{OH}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right) \leftrightarrow \mathrm{L}^{-}+3 \mathrm{H}_{2} \mathrm{O} & \mathrm{~K}_{\mathrm{c} 3 \mathrm{~A}} \tag{16}
\end{array}
$$

Where $\mathrm{HL}^{-}\left(\mathrm{H}_{2} \mathrm{O}\right)$ and $\mathrm{L}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ give the glutamic acid anion solvated with one and three water molecules, respectively (Figure 8). While, the $\mathrm{HL}\left(\mathrm{H}_{2} \mathrm{O}\right)$ is neutral arginine. Equations 15 and 16 are described by equilibrium constants ( $\mathrm{K}_{\text {с36 }}$ and $\mathrm{K}_{\mathrm{c} 3 \mathrm{~A}}$ ) which were theoretically calculated. The third ionization reactions of glutamic acid and arginine were determined by mixing Equations 15 with 4 and also, Equations 16 and 4:

The equilibrium constants Ka 3 G and Ka 3 A that define the Equations 15 and 16 are linked with constants $\mathrm{K}_{\mathrm{C} 3 G^{\prime}} \mathrm{K}_{\mathrm{C} 3 \mathrm{~A}}$ and $\mathrm{K}_{\mathrm{w}}$ by Equations 19 and 20:
$K_{a 36}=K_{c 36} \cdot K_{w}$
$K_{a 3 A}=K_{c 3 A} \cdot K_{w}$
Equations 19 and 20 were used to obtain the value of third ionization constants of glutamic acid and arginine in water. Figure 8 represents the structure of anionic glutamic acid.

Figure 8. Optimized structure of glutamic acid anions solvated with one (a) and three molecules of water (b) and practical numbering system accepted for performing the calculation.

Table 3. Values of $\mathrm{pK}_{\mathrm{a}}$ for the protonation of glutamic acid and arginine obtained using the Tomasi's method at the B3LYP/6-31+G(d) level of theory, at $T=298.15 \mathrm{~K}$.

For third ionization constant of arginine molecule, the same calculations and ratiocinations were done. The result of these calculations was shown in the Tables 3, 4 and also, Figures 5 and 6.

Figure 9 shows that the total free energy increases by increasing of number of solvation water molecules. Thus, it can be seen that the solvation of species is endothermic phenomena.

Number of solvation water molecules
Figure 9. Plot of the total energy ( $\mathrm{KJ} \cdot \mathrm{mol}^{-1}$ ) of solvated glutamic acid and arginine cations per water molecule against the total number of solvation water molecules.

## CONCLUSION

In the present study, different approaches are considered to develop a methodology for the accurate prediction of aqueous $\mathrm{pK}_{\mathrm{a}}$ values of protonated glutamic acid and arginine at $\mathrm{T}=$ 298.15 K. We have considered different reaction schemes for approximating the acid dissociation equilibrium; one distinct equation is used for the calculation of $\mathrm{pK}_{\mathrm{a}}$ values, and a number of levels of theory and empirical corrections are applied in the process of working toward this aim. The best correlations between the experimental and calculated data are obtained by Tomasi's method at the B3LYP/6-31+G(d)-PCM(opt) level of theory. Descriptors considered are the Gibbs free-energy change of the acid equilibrium in water, the charges on the acidic hydrogen, and on the basic nitrogen and the volume of the solvent cavity. The direct calculations differ significantly from the expected values, but the $\mathrm{pK}_{\mathrm{a}}$ values calculated using the correlation equations are very similar and in reasonable agreement with the expected $\mathrm{pK}_{\mathrm{a}}$ values. This research shows that ab initio method can be reliable to use with an acceptable degree of accuracy. These calculations can be useful for experimentalists and might be used for
improving the acidity scale for such weak organic acids.
