### Abstract

In this study, absorption spectra of sixteen azo dyes have been recorded in various solvents. These azo dyes have substituents such as OH, SO<sub>3</sub>H, Cl, I, NO<sub>2</sub>, C<sub>2</sub>H<sub>5</sub> and OCH<sub>3</sub> in different positions of phenyl ring. There is a shift in  $\lambda_{\text{max}}$  whose amount is dependent upon the type and position of substituent on the ring. The effects of substituent on the absorption spectra of azo dyes are interpreted by correlation of absorption maximum wavelengths (nm) with the hammett substituent parameters. Charge transfer transitions are observed in inverse direction for azo dyes with electron acceptor substituent compared to azo dyes with electron donor.

**Keyword:** Absorption spectra, azo dye, electronic charge transfer hammett substituent constant, non-linear optic,

---

### 1. Introduction

Azo dyes are used in different industrial fields such as printing, electronic photography, color formers, liquid crystal display, laser technology, data storage, optical actuators, photorefractive media, fiber dye, food and cosmetics industry (Matsu et al. 1970; Gibson et al. 1991; Bartkiewicz et al. 2001; Gimenez et al. 2005; So et al. 2006; Qian et al. 2007; Qui et al. 2007).

Application of azo dyes to high technology has been attracting much attention in recent years (Gregory 1991). It has also been demonstrated that azo dyes substituted with donor-acceptor terminal groups have many features as non-linear optical (NLO) materials. Moreover, the presence of donor and acceptor moieties in azo dyes can be interested in the study of solvatochromism (Masoud et al. 2005).

The development of correlation between UV-Vis. absorption and Hammett substituent constants is one of the major achievements of physical chemistry (Hansch et al. 1991). Hammett substituent coefficients ( $\sigma$ ) are used to evaluate the effect of the substituents upon the rate of a chemical reaction for which mechanism is known. Several studies were reported the correlation between UV absorption frequencies with substituent parameters (Issa et al. 1972; Kobayashi et al. 1987; Valentic et al. 1999; Ušćumlić et al. 2004; Mijin et al. 2006).

In our previous works, absorption spectra of azo dyes in different solvents were examined with linear solvation energy relationship using refractive index functions, dielectric functions and Kamlet-Taft parameters (Issa et

al. 1972; Gülseven et al. 2009; Sıdir et al. 2009; Gülseven Sıdir et al. 2011ab). In this present work, ultraviolet absorption spectra of 16 azo dyes have been recorded in the region of 200-600 nm in different solvents. Moreover, the substituent effect of sixteen azo dyes has been researched to correlate between  $\pi-\pi^*$  electronic transition bands wavelengths with Hammett substituent constants.

### 2. Experimental Section

All of the investigated azo dyes were synthesized and purified using a previously reported method (Ermis 2003; Aksu 2007; Yıldırım 2007). Molecular structures of researched azo dyes was shown in Table 1.

The DMSO, DMF, EtOH, THF, benzene, CCl<sub>4</sub>, 1,4-dioxane, cyclohexane organic solvents were used for spectroscopic measurements and were graded analytically by Sigma & Aldrich company. Each solution was prepared as about 2.10-5 M. All UV-vis spectra were acquired using Shimadzu UV-2550 spectrophotometer in standard 1 cm path length quartz cell at room temperature for spectral analysis.

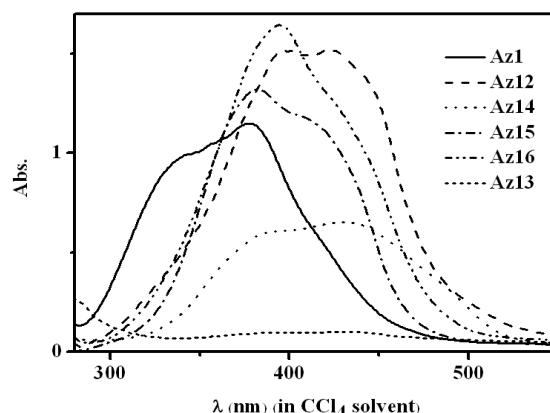

In each recording, the instrument was reset with the solvent before the spectra of the dyes were acquired. Sample recording was done from 200 nm to 600 nm.

AZ16	OH	I	H	H

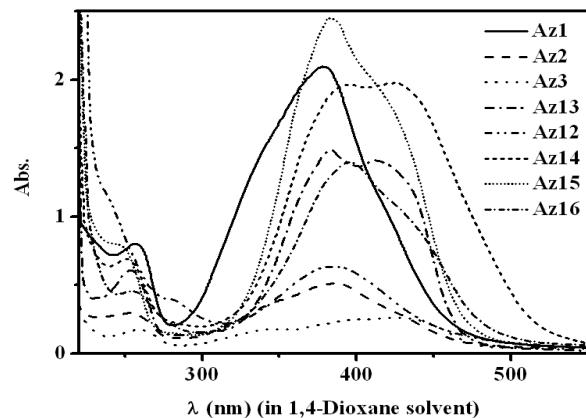

### 3. Results and Discussion

The characteristic absorption spectra of azo dyes recorded in DMSO, DMF, ethanol, THF, benzene, CCl<sub>4</sub> and 1,4-dioxane are listed in Table 2. As expected in non-polar solvents benzene and CCl<sub>4</sub>, azo dyes show three electronic absorption bands. These bands are due to the conjugation between the azo bridge and aromatic rings, the lone-pair located on the azo bridge and hydroxyl (OH) groups and intramolecular O-H...N hydrogen bond formation, respectively (Issa et al. 1972; Gülseven et al. 2009; Sıdir et al. 2009; Gülseven et al. 2011a; Gülseven et al. 2011b). According to Table 2, the induction of electrons in substituents (OH, OCH<sub>3</sub>, C<sub>2</sub>H<sub>5</sub>) of benzene ring produce

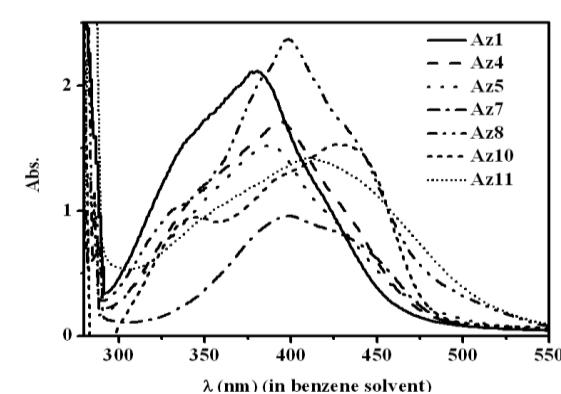

**Figure 1.** UV-Vis. spectra of investigated some azo dyes in the CCl<sub>4</sub> solvent.

bathochromic shifts on the band wavelength absorption maximum as compared to that of Az1 in solvents. On the contrary, the shift in maximum absorption wavelength does not depend on electron acceptor substituents in benzene rings (Issa et al. 1972; Kobayashi et al. 1987; Valentic et al. 1999; Ušćumlić et al. 2004; Mijin et al. 2006).

**Figure 2.** UV-Vis. spectra of investigated some azo dyes in the 1,4-Dioxane solvent.

**Figure 3.** UV-Vis. spectra of investigated some azo dyes in the benzene solvent.

Figures 1, 2 and 3 show UV-Vis spectra of some investigated azo dyes in CCl<sub>4</sub>, 1,4-dioxane and benzene, respectively. The  $\lambda_{\max}$  values of the Az4 and Az7 having o-Cl and o-I substitutions were shifted to 400 nm in the case of Cl and 487 nm in the case of I due to the fact that their inductive electron withdrawing and resonance electron donating effects impose on opposing effects on each other. For the case of o-I substitution, the electron with drawing inductive effect is smaller than those of Cl atom due to the lower electronegativity of I atom. Therefore, the resonance effect is slightly higher and I act as a weak electron donating group. The  $\lambda_{\max}$  value of Az1 is found to be almost equal to the  $\lambda_{\max}$  values Az2. In that, SO<sub>3</sub>H substituent in meta position does not effect the  $\lambda_{\max}$  values. According to  $\lambda_{\max}$  values of Az4 (o-Cl substituent) and Az6 (p-Cl substituent), rezonans effect of p-Cl is higher than inductive effect of o-Cl.

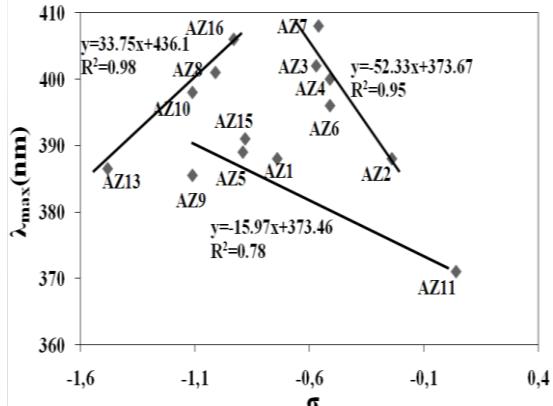

Azo dyes with an electron withdrawing group at one side of the molecule and an electron donating group at the other side are an example of the so-called push-pull molecules which are of interest in the field of non-linear optical molecules. The lowest energy electronic transitions correspond to n-π\* electronic transition gives rise to increasing the push-pull character of molecules (Kim et al. 2000; Kim et al. 2001). As seen from the all of

the figures, we can say that this molecule is the highest non-linear optical molecule among the investigated azo dyes, since the optic intensity of third band ( $n-\pi^*$  electronic transition) in Az14 is comparatively larger than those of the second band ( $\pi-\pi^*$  electronic transition).

The data given in Table 1 and Figures 1-3 confirm that the position of wavelength depend on nature of substituents. In order to ascertain the relationships between shifts in maximum absorption band and substituents, the absorption wavelength values of second electronic transition band, which is  $\pi-\pi^*$  electronic transition, seen from Table 1 were correlated by Hammett substituent constant as  $\sigma$  constant (Hansch et al. 1991). The plot of  $\lambda_{\max}$  versus  $\sigma$ T substituent constants for correlation in ethanol and DMSO solvents are shown in Figure 4 and 5, respectively. The three slopes of azo dyes were obtained in two solvents. For first solvent, linear correlation between total Hammett substituent constant ( $\sigma$ ) and  $\lambda_{\max}$  of Az1-Az5-Az9-Az15-Az11, Az2-Az3-Az4-Az6-Az7 and Az8-Az10-Az13-Az16 are founded to be  $R^2=0.78$ ,  $R^2=0.95$  and  $R^2=0.98$ , respectively.

**Figure 4.** Plot of  $\sigma$  vs  $\lambda_{\max}$  in the ethanol solvent.

In Figure 5, we have obtained  $R^2=0.948$  for Az2-Az6-Az8-Az10-Az16,  $R^2=0.9546$  for Az4-Az7-Az9-Az11-Az13-Az14-Az3 and  $R^2=0.9905$  for Az1-Az5-Az12-Az15. The summation of Hammett substituent coefficients ( $\sigma$ )

are used to reproduce these slopes. Positive  $\sigma$  value of the substituent gives rise to blue shift to  $\lambda_{\max}$  values of molecules.

**Figure 5.** Plot of  $\sigma$  vs  $\lambda_{\max}$  in the DMSO solvent.

On the contrary, if  $\sigma$  value is negative, which have electron accepting substituent, it cause red shift to  $\lambda_{\max}$  values of these molecules. The amount of shift in  $\lambda_{\max}$  values and the magnitude of  $(\lambda_{\max})X - (\lambda_{\max})H = \Delta\lambda_{\max}$  values are proportional to the electron donating ability and electron accepting ability of the substituent that depends on type and position of substituents. If the value of  $\Delta\lambda_{\max}$  is small, there is only inductive effect electronic absorption spectrum. The presence of resonance effect increases the value of wavelength shift in absorption spectra. The highest  $\Delta\lambda_{\max}$  is observed when both inductive and resonance effects come together. Investigated azo dyes show mostly bathochromic effect. When azo dyes have electron donor properties, it brings about bathochromic effect due to increasing conjugation and so photosensitization (Gülseven et al. 2009; Sıdir et al. 2009; Gülseven Sıdir et al. 2011ab).

On the other hand, azo dyes have the electron accepting properties which decrease conjugation and, thus, photosensitization of these molecules hardly depend to include both intermolecular and intra molecular hydrogen bonding. These molecules comes into being hypsochromic effect depending on properties of solvents (Kim et al. 2000).

The substituents of benzene rings (A and B rings) have a donor or acceptor properties, so, they exhibit antagonizing and/or additive effect on charge transfer interaction between the two moieties. The electron donating and electron accepting substituents on A benzene ring decrease the energy gap between the ground and excited states of the molecules. The scopes of  $\lambda_{\max}$  as a function of the  $\sigma$  (sum of Hammett substituent constant) give two straight lines with opposite slopes, indicating the applicability of the Hammett equation in the form (Issa et al. 1972):

$$(\lambda_{\max})X = (\lambda_{\max})H + \rho(\sigma)X$$

As can be seen from Figure 4, the Az16, Az8, Az10 and Az13 dyes in ethanol solvents have electron accepting properties due to  $\rho=33.75$ . On the contrary, if  $\rho$  have -52.33 and -15.97, these molecules in ethanol solvents have electron donating properties. Since the  $\rho$  value of Az13, Az14, Az7, Az3 and Az11 dyes in DMSO are 11.92, these molecules are electron acceptor. On the other hand, when  $\rho$  is -16.67 and -40.52, molecules in DMSO solvent are electron donor. Moreover, the change in  $\rho$ 's sign indicates that the charge transfer between the two benzene rings for two directions.

We can say that in case of electron accepting azo dyes in direction of charge transfer is B→A with high interaction, while in case of electron donating azo dyes in direction of charge transfer is A→B with poor interaction due to the antagonization effects of the OH substituents of B ring. Azo dyes on the same slopes have same electronic transition mechanism.

#### 4. Conclusion

The absorption spectra of sixteen azo dyes having different substituents such as OH, SO<sub>3</sub>H, Cl, I, NO<sub>2</sub>, C<sub>2</sub>H<sub>5</sub> and OCH<sub>3</sub> have been evaluated by using UV-vis. spectra in various solvents. The effects of substituent on the electronic absorption spectra of azo dyes are investigated by correlations between absorption

maximum wavelengths (nm) and the Hammett substituent parameters. The charge transfer in these molecules was determined by these correlations.
