Abstract

The cytotoxicity of propolis against tumor cells has been widely reported\textsuperscript{1}. Propolis from tropical areas present components such as triterpenes, diterpenes and benzophenones\textsuperscript{2}, however, new types of propolis may be recognized and their biological activities need to be elucidated. Therefore, four Colombian propolis samples were chemically characterized by gas chromatography-mass spectrometry (GC–MS) and their cytotoxic action against canine osteosarcoma (OSA) cells was determined, as well as apoptosis induction and changes in gene expression of \textit{CASPASE 8} and \textit{CASPASE 9}. OSA cells were treated with ethanolic extracts of propolis; the lactate dehydrogenase (LDH) assay and the annexin V/propidium iodide kit were used to evaluate the cytotoxic effect and apoptosis induction, respectively. Changes in gene expression were evaluated by quantitative real time PCR (qPCR). The propolis samples were rich in diterpenes, triterpenes and benzophenones. Propolis samples induced a cytotoxic effect towards OSA cells that was correlated to the LDH leakage into the culture medium after cell membrane rupture. The cytotoxic effect increased in a time-concentration manner after incubation with propolis and the cytotoxic concentration 50\% (CC\textsubscript{50}) was lower than 36.24 µg/ml after 72 h of treatment. Colombian propolis samples induced total apoptosis significantly (untreated cells: 10.77 ± 2.22\%; treated cells: from 58.403\% ±1.39 to 95.97 ± 2.14\% after 48 h). All propolis samples increased the expression of \textit{CASPASE 8} and three of them induced the expression of \textit{CASPASE 9}. Colombian propolis samples induced apoptosis in canine OSA cells, suggesting their promising potential as new strategies for cancer therapy.
