ABSTRACT

In this study, antibacterial effects of the pomegranate peel extract against food pathogens were investigated. Different concentrations of pomegranate peel extract (2.5, 5, 7.5 and 10%), which showed the highest antibacterial effect in vitro experiments were added to the alginate film. Mackerel fillets coated with the film solution prepared in this way were stored at 4±1 °C for 13 days. L. monocytogenes, total aerobic mesophilic bacteria, total aerobic psychrophilic bacteria, total yeast-mould and enterobacteriaceae counts were determined on 0, 3rd, 8th, and 13th day of storage period.

At the end of the study; it was determined that the pomegranate extract was effective and the inhibition effect was also increased based on the increase in extract concentration. Different concentrations of pomegranate peel extract showed antibacterial effect against L. monocytogenes, E. coli O157:H7, and S. aureus (P<0.05). As a result of 13 days storage of mackerel fillets coated with alginate enriched with 2.5, 5, 7.5 and 10% PPE at 4 °C, the number of L. monocytogenes significantly decreased (P<0.05). During the storage period total aerobic mesophilic bacteria and enterobacteriaceae number were found to be significantly lower in the experimental groups used pomegranate peel extract in comparison with the control group. As a result, it was determined that pomegranate peel extract has a potential to be used as a natural preservative in seafood products.

Keywords: Pomegranate peel extract; Antimicrobial film; L. monocytogenes

1. Introduction

The Listeria monocytogenes is a gram-positive, asporous, facultative anaerobic bacterium that causes listeriosis from foodborne diseases. It has been reported that most of the listeriosis outbreaks occur through ready-to-eat foods such as dairy products, salads, seafood, processed meats and poultry (Chan & Wiedmann 2009). Synthetic antimicrobial agents are widely used to prevent the development of pathogenic bacteria such as L. monocytogenes in foods, but concerns about the safety of these chemicals are increasing day by day (Owen & Palombo 2007). For this reason, the fruits, vegetables, spices, plants or their extracts that are enrich in terms of phenolic compounds are used to avoid the development of pathogenic or spoilage bacteria and to prolong the shelf life of food (Rawdkuen et al 2012).

Today, the use of agricultural food industry’s by-products or wastes has become one of the
The L. monocytogenes, Escherichia coli, Escherichia coli O157:H7, Bacillus cereus, Salmonella enteritis and Staphylococcus aureus were procured from İzmir Katip Celebi University Aquaculture Faculty culture collection.

2.2. Method

2.2.1. Preparation of the extract

The pomegranate peel were dried in drying oven at 50 °C. These dried samples were shredded to small pieces by a wiring blender. 20 g of dried samples were extracted with 100 mL solvent (80% ethanol). The mixture was kept in a shaking water bath for 6 hours at 50 °C and was filtered. This process was repeated 4 times. This latter was evaporated in a rotary evaporator, finally freezeed and lyophilised (Feresin et al 2000; Keyrouz et al 2011).

2.2.2. Preparation of bacterial inoculums

The stock cultures of L. monocytogenes, E. coli, E. coli O157:H7, B. cereus, S. enteritis and S. aureus that are in liquid form were stored at -20±2 °C on glycerol containing (20%; v v⁻¹). For the experiments, 100 μL of stock cultures were transferred to 10 mL MHB medium, and the bacteria were activated by incubation at 30 °C for 24 hours.

2.2.3. Disk diffusion method (Kirby-Bauer method)

The disk diffusion method was used to determine the antibacterial activities of pomegranate peel extracts (Melendez & Capriles 2006). 25 μL (0.25, 0.50, 1, 1.5, 2.5, 5, 7.5 and 10% concentrations) of pomegranate peel extracts were soaked into sterile empty discs placed in petri dishes in which planting was made. The petri dishes in which planting were made were left to the incubation process at 30 °C for 24 hours. The activation process was repeated twice.

2.2.4. Preparation of film solution and application to mackerel fillets

Sodium alginate (Kimbiotek) and CaCl₂ (Merck) were used to prepare the film solution. 30 g of sodium alginate was mixed with 1000 mL of distilled water and adjusted to 80 °C. The mixture kept in
a magnetic stirrer. After having been cooled until 50 °C, the pomegranate extracts at concentrations of 2.5, 5, 7.5 and 10% were added into it. 50 g of mackerel fillets were inoculated by spreading \textit{L. monocytogenes} to a final concentration of $10^4$ CFU g$^{-1}$. Then the fillets were immersed in 3% alginate solution containing 2.5, 5, 7.5, 10% PPE and left for 1 minute. The samples coated with alginate film without PPE were used as control. This process has been repeated twice. Fillets coated with alginate were immersed in the 2% CaCl$_2$ solution and kept (3 minute) for solidification (Song et al 2011). The fillets prepared like this were packaged and stored in the refrigerator ($4\pm1$ °C) for 13 days.

2.2.5. Determination of the number of \textit{L. monocytogenes} in mackerel fillets coated with alginate film

The number of \textit{L. monocytogenes} were determined on 0, 3$^{rd}$, 8$^{th}$, and 13$^{th}$ day of storage period. For this, the mackerel filet was transferred to the Maximum Recovery Diluent (MRD) solution and homogenized. It was diluted up to the dilutions of $10^6$ from homogenate taking into account the $10^{-1}$ dilution rate, and planting according to the Most Probable Number (MPN) method. For this purpose, 1 mL of the appropriate dilutions was transferred to a 10 mL Fraser broth medium, and incubated at 37 °C for 24 hours. The number of \textit{L. monocytogenes} was determined by being evaluated the tubes in which the growth was occurred after the incubation (Halkman 2005).

2.2.6. The microbiological analysis on mackerel fillets coated with alginate film

The number of total aerobic mesophilic bacteria, total aerobic psychrophilic bacteria, total yeast-mould and enterobacteriaceae were performed on 0, 3$^{rd}$, 8$^{th}$, and 13$^{th}$ day of storage period.

The mackerel filet was transferred to the Maximum Recovery Diluent (MRD) solution and homogenized. 0.1 mL was taken from the appropriate dilutions and planted in petri dishes containing nutrient with spreading method. PCA was used for TAMB and incubated for 24-48 hours at 30 °C; PCA was used for TAPB and incubated for 10 days at 6.5 °C; PDA was used for TYM counts and incubated for 4-5 days at 30 °C; and VRBA was used for enterobacteriaceae count and incubated for 24 hours at 37 °C. Bacterial counts were determined by counting the colonies growing on the medium at the end of incubation (Harrigan 1998).

2.2.7. Statistical analysis

The obtained data were analyzed using ANOVA (analysis of variance). The results were evaluated by Duncan Multiple Comparison Test. The SPSS statistical package program was used to test whether there is any difference between the application groups (IBM SPSS 2012).

3. Results and Discussion

3.1. Antibacterial activities of extracts

Antibacterial properties of extracts obtained from pomegranate peel were investigated in this study. The inhibition zone diameters of the extracts against the tested microorganisms were given in Figure 1. Different concentrations of PPE have antibacterial effect against \textit{L. monocytogenes}, \textit{E. coli} O157:H7 and \textit{S. aureus} (P<0.05). Similar results have been identified by different investigators. Al-Zoreky (2009) reported that PPE could be used for the inactivation of \textit{L. monocytogenes}, \textit{S. aureus}, \textit{E. coli}, and \textit{Yersinia enterocolitica}. Prashanth et al (2001) the highest inhibitory effect was obtained in \textit{P. vulgaris} and \textit{B. subtilis}. Ahmad & Beg (2001) determined that extracts of pomegranate displayed antibacterial effect against \textit{S. aureus}, \textit{E. coli} and \textit{Shigella dysenteriae}.

It was determined that the inhibition effect also increased based on increasing in PPE concentration. The highest inhibition zone was obtained from 10% PPE and the zone diameters for \textit{S. enteritis}, \textit{B. cereus}, \textit{E. coli} O157:H7, \textit{E. coli}, \textit{S. aureus} and \textit{L. monocytogenes} were determined as 18, 22, 24, 17, 16 and 23 mm, respectively. Al-Zoreky (2009) found these zone diameters as 17, 16, 13 and 20 mm for \textit{Bacillus}, \textit{E. coli}, \textit{S. aureus} and \textit{L. monocytogenes}, respectively. In the study in which Dahham et al
(2010) determined that the inhibition zone diameters obtained from pomegranate peel were in the length of 25 mm for \textit{B. cereus}, 20 mm for \textit{E. coli} and 25 mm for \textit{S. aureus}. Whereas Melendez & Capriles (2006) found these as 12 mm for \textit{E. coli} and 22 mm for \textit{S. aureus}. Mathabe et al (2006) reported that the extracts obtained from pomegranate are effective on \textit{S. aureus}, \textit{E. coli}, \textit{Salmonella typhi}, \textit{Vibrio cholera}, \textit{S. dysenteriae}, \textit{S. sonnei}, \textit{S. flexneri} and \textit{S. boydii}, and that they had the inhibition zones whose diameters were between 12 and 31 mm.

According to the results obtained by Hayrapetyan et al (2012), \textit{L. monocytogenes}, \textit{Bacillus subtilis}, \textit{B. cereus}, \textit{E. coli} and \textit{S. aureus} showed susceptible to PPE, respectively. According to the result that were obtained by them, \textit{S. aureus}, \textit{B. cereus}, \textit{E. coli} and \textit{B. subtilis} bacteria were found to be more sensitive to PE compared to \textit{L. monocytogenes}. \textit{S. aureus} were reported to show the highest sensitivity among the tested microorganisms. The results that we obtained are similar to those of other researchers, and it was determined that PPE can be used effectively against many food pathogens.

3.2. Changes in \textit{L. monocytogenes} number of mackerel fillets during refrigerated storage

The number of \textit{L. monocytogenes} detected during storage (0, 3, 8 and 13. days) of mackerel fillets coated with alginate film containing PPE at 4 °C is given in Figure 2.

The number of \textit{L. monocytogenes} on mackerel fillets was significantly higher (P<0.05) for untreated samples than for treated samples. But the difference between PPE treated groups was not statistically significant (P>0.05). At the beginning of storage, the number of bacteria that had been 10^{4} MPN g^{-1}, was determined after 8 day storage as 4.3x10^{3} MPN g^{-1} in the control group and 7.4x10^{1} MPN g^{-1} in the samples treated with 10% PPE. At the end of 8 days of storage, the number of \textit{L. monocytogenes} decreased significantly due to the increase in the extract concentration. The antibacterial effect of PPE was determined on many bacterial species in both
in vitro and in vivo conditions. It was determined that the PPE prepared by Al-Zoreky (2009) using 80% methanol has an inhibitory effect against *L. monocytogenes, S. aureus, Escherichia coli* and *Yersinia enterocolitica*. The methanolic of PPE caused decreasing more than 1 log in the number of *L. monocytogenes* of the fish stored at 4 °C. At the last of the 46-day storage period and at 4 °C, Hayrapetyan et al (2012) found that the number of *L. monocytogenes* of meat patties that of the controls and samples treated with 7.5% of were 4.1 log CFU g⁻¹, 9.2 log CFU g⁻¹, respectively. Wu et al (2016), in an experiment conducted on the survival level of *L. monocytogenes* and *V. parahaemolyticus* in the cooked shrimp and raw tuna fish which PPE was applied, they found that the count of *L. monocytogenes* in the samples was 2 log less than the control group.

### 3.3. Changes in the number of TAMB, TAPB and enterobacteriaceae in mackerel fillets during refrigerated storage

The change in the number of TAMB during 13 days of storage (0, 3, 8 and 13 days) is given in Figure 3a. The count of TAMB was determined less in all groups with PPE than the control group. As the PPE concentration increased, the number of TAMB decreased significantly. At the end of 13 days of storage at 4 °C the lowest number of TAMB was detected in the experimental group to which was applied 10% PPE (P<0.05).

The number of TAMB (means±standard errors) of the controls and of samples treated with 2.5, 5, 7.5 and 10% PPE were 6.96±0.03, 6.53±0.20, 6.46±0.11, 6.41±0.04 and 6.18±0.02 log CFU g⁻¹, respectively, at the last of the storage period.

![Figure 3- Changes in the number of TAMB (a), TAPB (b), enterobacteriaceae (c) and TYM (d) in mackerel fillets during refrigerated storage. (A, control group-without PPE; B, samples treated with 2.5% PPE; C, samples treated with 5% PPE; D, samples treated with 7.5% PPE; E, samples treated with 10% PPE)](image)
The change in the total number of TAPB is given in Figure 3b. At the end of storage (day 13), the number of TAPB of the controls and of samples treated with 2.5, 5, 7.5 and 10% PPE were determined as 5.35±0.05, 5.11±0.07, 5.35±0.12, 5.34±0.26 and 5.31±0.23 log CFU g⁻¹, respectively. The results indicated that there was no significant differences among the groups in terms of TAPB during the storage period (P>0.05).

The change in the TYM counts is given in Figure 3c. On the 13th day of storage, TYM counts of the controls and of samples treated with 2.5, 5, 7.5 and 10% PPE were determined as 6.60±0.05, 6.34±0.02, 6.27±0.01, 6.15±0.05 and 6.09±0.07 log CFU g⁻¹, respectively. Significant differences between TYM levels of control and other groups have not been observed (P>0.05).

The change in the number of enterobacteriaceae in the mackerel fillets stored at +4 °C is given in Figure 3d. When compared with the control group, the number of enterobacteriaceae was determined to be lower in the groups to which samples treated with 10% PPE (P<0.05). At the end of storage, the number of enterobacteriaceae controls and of samples treated with 2.5, 5, 7.5 and 10% PPE were determined as 6.57±0.31, 6.07±0.14, 6.01±0.14, 5.88±0.18 and 5.53±0.13 log CFU g⁻¹, respectively. Although the lowest number of the enterobacteriaceae were observed in the group to which 10% PE was applied, the number of enterobacteriaceae and TAMB showed a significant decrease as the extract concentration increased (P<0.05). Berizi et al (2016) investigated the effect of 1, 2, 4% PPE on the quality of trout for 18 months at -18 °C. At the end of storage, the lowest TAPB counts were detected in trout to which 4% PPE was applied. At the end of storage, number of TAPB controls and of samples treated with 1, 2 and 4% PPE were determined as 5.14, 4.87, 4.86 and 4.27 CFU g⁻¹, respectively. In addition, the count of enterobacteriaceae was determined to be lower in the trout samples to which 1, 2 and 4% PPE was applied in comparison with the control group. It was reported that the development of TAMB significantly was suppressed in the groups to which 0.1, 0.2 and 0.3% PPE was added compared to the control group in the study carried out by Özdemir et al (2014). Furthermore, as the concentration of the extract increased, the number of enterobacteriaceae also decreased significantly. The results that we obtained are similar to these studies, and it was seen that the antibacterial quality increases as the extract concentration increases. Contrary to these studies, it was reported that the increase in extract concentration did not increase the antibacterial effect in the study conducted by Basiri et al (2014). These investigators investigated the impact of vacuum packaging and PPE on the quality of pacific white shrimp stored at +4 °C for 10 days. TAPB, LAB and enterobacteriaceae numbers were found to be lower than the control group in the PPE supplemented groups.

4. Conclusions
The antibacterial effect of PPE on the food pathogens were investigated in this study. It was determined that the PPE have antibacterial effect and that the antibacterial effect significantly increased as the extract concentration increased. It was determined that PE which has antibacterial effects on many food pathogens, primarily on L. monocytogenes, can be used as a natural preservative in seafood products.
