Abstract

Aim of study: This study was conducted to determine the biological richness of spiders from Sinop province, Turkey.

Area of study: The studies were carried out on between 41° 12' and 42° 6' northern latitudes and 34° 14' and 35° 26' east longitudes within the Sinop province borders.

Material and Methods: Spiders were collected from 2009 to 2015 using four collection methods: using sweep netting, tree beating, active searching and pitfall trapping.

Main results: A total of 1766 specimens were collected that represented by 31 families, 133 genera and 200 species. The most diverse families collected are the Salticidae (29 spp.), Theridiidae (29 spp.) and Gnaphosidae (21 spp.). According to previous studies and this work, 31 families, 139 genera, 212 species of spiders are present in Sinop province, of which 192 species are recorded for the first time.

Research highlights: Furthermore, one genus (*Theridula* Emerton 1882) and three species, namely *Asagena meridionalis* Kulczyński 1894, *Theridion boesenbergi* Strand 1904 and *Theridula gonygaster* (Simon 1873), are new records for Turkey, and are provided with illustrations. Here, we provide the first annotated checklist of the spider species of Sinop province.

Keywords: Species richness, Sinop, *Araneae*, Fauna, new records, checklist

Detaylı Tür Listesini İçeren, Sinop İli Yeni Örümcek (*Arachnida: Araneae*) Kayıtları

Öz

Çalışmanın amacı: Bu çalışma, Sinop örümceklerinin biyolojik zenginliğini belirlemek amacıyla yapılmıştır.

Çalışma alanı: Çalışmalar, Sinop İl sınırları içinde, 41° 12' ve 42° 6' kuzey enlemleri ve 34° 14' ve 35° 26' doğu boyamlarında gerçekleştirilmiştir.

Materyal ve Yöntem: 2009-2015 yılları arasında yapılan arazi çalışmalarında örümcek örnekleri dört yöntem; atrap, dallara vurma, çevrede arama ve çukur tuzak kullanarak toplanmıştır.

Temel Sonuçlar: İncelenen toplam 1766 örneğin, 31 familya bağlı 133 cins ve 200 türe ait olduğu tespit edilmiştir. En çok dağılış gösteren familyalar sırasıyla; Salticidae (29 tür), Theridiidae (29 tür) and Gnaphosidae (21 tür)'dır. Daha önce yapılmış olan çalışmalar ve bu çalışma birlikte değerlendirildiğinde, 31 familya, 139 cins ve 212 türün Sinop'ta dağılış gösterdiği tespit edilmiştir. Bahsedilen bu türlerden 192 tür Sinop İl'i için yeni kayıttır.

Araştırma vurguları: Araştırma alanından bir cins (*Theridula* Emerton 1882) ve üç tür, *Asagena meridionalis* Kulczyński 1894, *Theridion boesenbergi* Strand 1904 and *Theridula gonygaster* (Simon 1873), Türkiye için yeni kayıttır. Ayrıca, bu çalışma ile Sinop'un örümcek türlerinin kontrol listesi ilk kez verilmektedir.

Anahtar Kelimeler: Tür zenginliği, Sinop, *Araneae*, fauna, yeni kayıt, kontrol listesi

Introduction

Currently, 4076 genera and 47297 spider species are classified in 116 families (World Spider Catalog, 2018). A large variety of spiders, are found in quite different terrestrial and fresh water habitats; from the peaks of

Everest to caves and houses (Bayram, 1987). Spiders are also hunted by other predators hunting for insects. They can reach 1000 individuals per square meter under suitable conditions. Spiders that are so dense in nature are thought to be able to stabilize

insect populations. Therefore, their role in protecting the natural balance, biocontrol availability, and their nutritional ecology in agricultural ecosystems are being investigated thoroughly (Nyffeler and Benz, 1987).

Compared with the number of spiders known in the world, studies on spider systematics and fauna in Turkey are limited. Turkey's spider fauna was studied for the first time by Karol in 1967. Karol (1967) has published a Preliminary List of Spiders of Turkey I. According to this list, 302 species belonging to 119 genera, 30 families, are found in Turkey. In later years, Bayram (2002) and Demirsoy (2002) have contributed to the subject with the book "Zoogeography of Turkey". Accordingly, there are 162 genera and 520 species belonging to 44 families, and six subspecies in Turkey. Topçu, Demir & Seyyar (2005) published a checklist of spiders of Turkey. They state that there are 613 species belonging to 43 families, and two subspecies. Later, 332 genera belonging to 53 families, 1022 species, were listed (Bayram, Kunt & Danışman, 2017). The new list provided by Demir and Seyyar (2017) raises the total number of species known for Turkey to 1117 plus two subspecies, grouped in 339 genera and 52 families. However, there are no studies on the diversity of spiders in Sinop and the few previous records are due to sporadic collections. Brignoli (1978) reported 3 families, 5 genera and 5 species for Sinop. After that, Buchar and Dolanský (2011), Danışman, Erdek & Coşar (2012a), Danışman, Erdek, M., Sancak, Z., Coşar (2012b,c) Danışman and Coşar (2016), Danışman (2014), Özktük, Kunt, Karakaş & Danışman, (2015), Coşar (2015), Coşar and Varol (2016), Coşar, Danışman & Tarlabölen (2016), Coşar, Danışman & Kartaler (2017) and Logunov and Demir (2006) found new records for 14 species of 12 genera of 8 families. Until 2018, 11 families, 17 genera and 19 species have been reported from Sinop province, which is consistent with the above information.

The aim of this study is to contribute to the spider fauna of the Central Black Sea Region and Turkey, which is not very well

investigated. Moreover, a preliminary checklist for Sinop province is provided.

Material and Methods

Study Area

Sinop is located between $41^{\circ} 12'$ and $42^{\circ} 6'$ northern latitudes and $34^{\circ} 14'$ and $35^{\circ} 26'$ east longitudes, in the region where the Eastern and Western Black Sea climates are intertwined. In the Black Sea Region, the sea increases the humidity of the region and does not allow the increase of temperature differences in the coastal regions. However, because of their highness, the climatic characteristics of the mountains facing north and south are different. Due to the mountains running parallel to the coast in the province of Sinop, there is no maritime climate. The climate in the coastal zone is moderate. The climate changes in distant districts, such as Boyabat, Durağan and Sarayönü. In these districts, a transition climate zone is observed between the Black Sea climate and the continental climate of Central Anatolia (Anonymous, 2012).

According to the 14-year observations obtained from the Sinop Meteorology Station Directorate, average annual temperature is 14.8°C and average annual precipitation is 64.1 mm.

The natural vegetation is rich and diverse because the Black Sea climate is rainy throughout the year. The soil structure is very suitable for the growth of woody herbs since it has a stony, clayey and calcareous sandy character. There are forest, maquis frigana, sand dune, stream, marsh and lake vegetation types. The natural vegetation covers the forests. Climate transition is also evident in the floristic structure. Mediterranean vegetation is also found along the coastline of the province; the climate starts to become dry towards the south. For this reason, the lush vegetation cover in the north replaces steppe plants. The main tree species on the coastline of the province are pine, beech, hornbeam, oak, linden, plane-tree, poplar and chestnut. As the altitude increases, yellow pine, fir, ash, and elm trees are found. Due to higher in the forest understory, plant density on the forest floor is higher (Baysal, 2008; Öztürk, 2010).

Material

Spiders were collected from 67 different localities. A total of 1766 adult specimens were collected from Sinop and its vicinity (Fig. 1) and 31 families were found. The

study localities, with their coordinates, elevation and sampling dates, are numbered and given in Table 1.

Figure 1. Map of Sinop Province and its environs; numbered localities are presented in Table 1.

Table 1. List of localities where the spider were collected

We used hand collecting, soil and litter sampling, beating and/or sweeping vegetation, and pitfall trapping to collect spiders from rocks (underneath), crevices, logs and debris; under loose bark of dead trees, stumps and the forest understory.

Captured spiders were transferred by aspirator to small jars or vials containing 70% ethyl alcohol. In the laboratory, all spiders were sorted, counted and identified using appropriate literature. All collected spiders were taken to the laboratory, placed in small dishes, submerged in alcohol, and examined using stereo-zoom microscopes.

We used the identification keys of Nentwig, Blick, Gloor, Hänggi & Kropf (2017), and followed the World Spider Catalog (2018) for the nomenclature and taxonomy of spiders. Voucher specimens were stored in 70% ethanol and deposited in the Department of Biology, Faculty of Science and Art, Sinop University, Sinop. Specimens were photographed using a Canon

EOS 70D camera attached to a Zeiss Stemi 2000-C stereomicroscope.

For consistency purposes, we follow the currently accepted names, as listed in the World Spider Catalog (2018). Family order is based on the database prepared by Bayram, Kunt & Danışman (2017). The species name and genus are sorted in alphabetical order.

Results and discussion

Spider families, species and locality numbers are listed in order for convenience. After each listed species, the distribution by realm (Palaearctic, Holarctic, Cosmopolitan etc.) is given, based chiefly on the designations (Table 2). In addition, the number of male and female individuals collected for each species and the total number of individuals caught by family members are also included in Table 2. Subadult individuals are not included in this list.

Table 2. Families and species, distribution, localities and number of male and female spiders collected in Sinop

Family: SCYTODIDAE

Taxon	Distribution	Locality	♂	♀
<i>Scytodes thoracica</i> (Latrelle 1802)	Holarctic, Pasific	[1.1] [5] [30] [39] [38] [37] [47]	3	9
Total			12

*New record for Turkey

A total of 1766 adult (627 male and 1139 female) spiders were collected, representing 200 species belonging to 133 genera in 31 families; 35.50% of the spiders collected were male and 64.50% female. Most of the species in the study area are Palearctic in terms of their distribution. During the field trips, only some male or female individuals were found for some of the species obtained from the research area. The most species-rich spider families are the Theridiidae (29 spp.) and the Salticidae (29 spp.) followed by the Gnaphosidae (21 spp.), Araneidae (20 spp.), Linyphiidae (20 spp.), and Thomisidae (16 spp.) (Table 2). The most abundant family in the field was the Araneidae (14%), followed by the Linyphiidae (13%), Theridiidae (12%), Salticidae (12%), Lycosidae (8%), Gnaphosidae (7%), and Dictynidae (7%) (Figure 2). Sancak (2007) reported that the most abundant family was the Lycosidae, followed by the Araneidae, Theridiidae, Linyphiidae and Salticidae from the Eastern Black Sea Region. All the genera of the families Amaurobiidae, Liocranidae, Miturgidae, Oecobiidae, Phrurolithidae, Scytodidae, Sparassidae, Titanocidae and

Zodariidae found were represented by one species each (Table 2).

The prevalence of the Araneidae, Linyphiidae and Theridiidae in the samples is probably due to the sampling method used. Many of our collected grass-dwelling and ground-dwelling spiders (Araneidae, Linyphiidae and Theridiidae) are usually associated with low vegetation. The grass-dwelling and ground-dwelling spider species were mostly obtained using both methods (sweep-netting and beating sheet). Besides, since the sweep-netting in our study was carried out only during the daytime, it was restricted to diurnal spider species (e.g. families Pisauridae, Salticidae and Oxyopidae), while the pitfall traps collected both diurnally active spiders (Lycosidae and Zoridae) and nocturnally active ones (Clubionidae, Gnaphosidae and Liocranidae). The ground-dwelling spiders were collected using pitfall traps; trapping was continuous, with traps being kept open from 2009 to 2012. For this reason, this study is poor in terms of nocturnal species and ground-dwelling spiders.

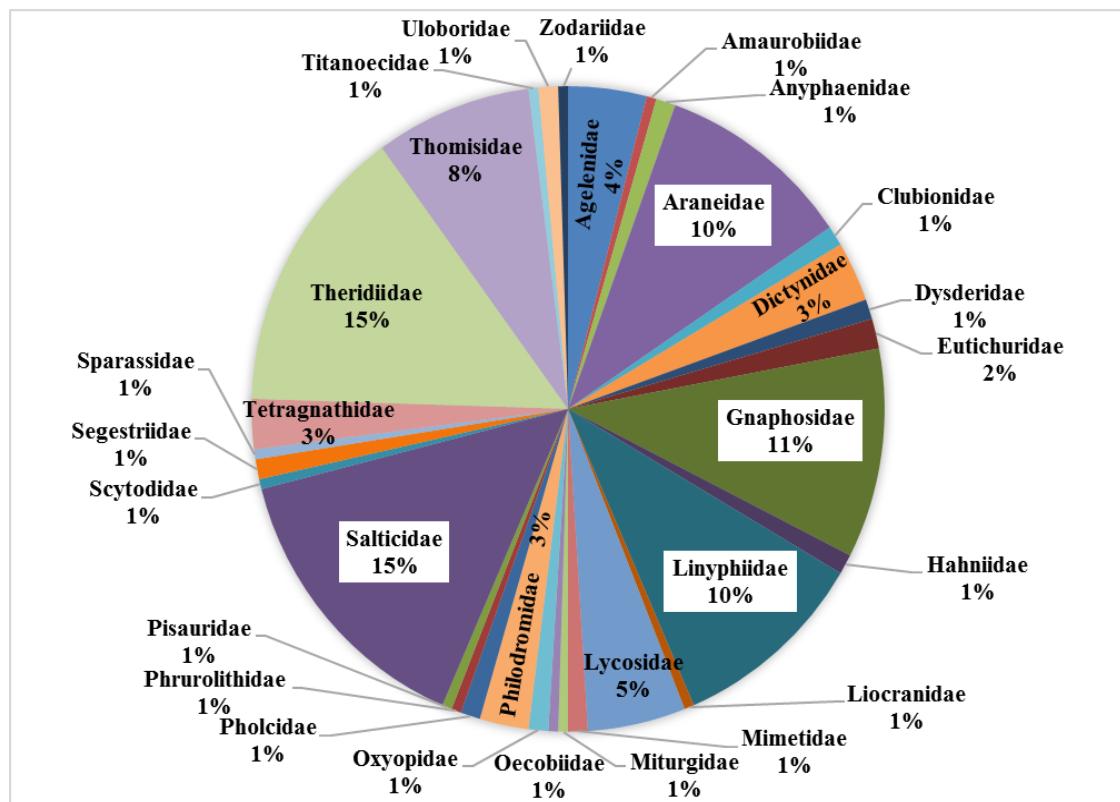

Figure 2. Percentage of species richness per family of spiders recorded in Sinop

Frontinellina frutetorum (C.L. Koch 1834), *Anelosimus vittatus* (C. L. Koch 1836), *Mangora acaylpha* (Walckenaer 1802) and *Amaurobius erberi* (Keyserling 1863) are the most common species in different localities, while the following species were found in a few localities, but they were sampled in higher numbers in the same localities: *Zilla diodia* (Walckenaer 1802) and *Nigma flavescens* (Walckenaer 1830).

In a faunistic study on the Linyphiidae family in the Black Sea Region, 14 genera and 17 species were recorded (Karabulut, 2011; Karabulut and Türkeş, 2011). In our study, 18 genera and 22 species belonging to the Linyphiidae family were found. The following species are common to both studies: *Linyphia hortensis* Sundevall 1830, *Linyphia triangularis* (Clerck 1757), *Centromerus sylvaticus* (Blackwall 1841), *Neriene peltata* (Wider 1834), *Neriene radiata* (Walckenaer, 1841), *Frontinellina frutetorum* (C.L. Koch 1834) and *Lepthyphantes leprosus* (Ohlert 1865).

The following spider species collected from the study area are known venomous

spiders: *Argiope lobata* (Pallas 1772), *Larinoides cornutus* (Clerck 1757), *Araneus diadematus* Clerck 1757 belonging to family Araneidae; *Cheiracanthium mildei* (C.L. Koch 1864) to family Eutichuridae; *Segestria florentina* (Rossi 1790) to family Segestriidae; *Steatoda grossa* (C.L. Koch 1838) and *Steatoda paykulliana* (Walckenaer 1805) to family Theridiidae (Bayram et al., 2007). Some species, namely, *Alopecosa taeniopus* (Kulczyński 1895), *Myrmarachne formicaria* (De Geer 1778), *Orthobula charitonovi* (Mikhailov 1986), *Cyclosa oculata* (Walckenaer 1802), *Cicurina paphlagoniae* Brignoli 1978, *Walckenaeria furcillata* (Menge 1869) and *Clubiona terrestris* Westring 1851 *Coelotes sinopensis* (Danışman, Karanfil & Coşar 2016), *Pellenes seriatus* (Thorell 1875), *Saitis barbipes* (Simon 1868), *Walckenaeria cirriceps* Thaler 1996 that were previously reported for Sinop province (Topçu, Demir, & Seyyar, 2005; Buchar and Dolanský, 2011; Danışman et al., 2012a, 2012b, 2016; Danışman, 2014; Danışman and Coşar, 2016; Brignoli, 1978; Coşar and Varol, 2016) were not found during this study (Table 3). In

addition, Brignoli (1978), Coşar (2015), Danışman, Coşar, Erdek & Sancak (2012d), Logunov and Demir (2006), Özktük et al., (2015) and Coşar et al., (2017) reported species such as *Neoscona adianta* (Walckenaer 1802) *Mangora acalypha*

(Walckenaer 1802), *Xysticus kochii* Thorell 1872, *Pseudicius picaceus* (Simon, 1868) *Harpactea korgei* Brignoli 1979 and *Haplodrassus minor* (O.P.-Cambridge 1879) that were also collected during the present study (Table 3).

Table 3. Spiders according to records published until 2018 and results of this study

Family <i>species</i>	Previously Reported	Present Study
Family: Dysderidae

<i>Pseudicius picaceus</i> (Simon, 1868)	Danışman et al. 2012b, 2012a	✓
<i>Neon levius</i> (Simon, 1871)	Coşar 2015	✓

Regarding the new records for Turkey, one genus and three species have not been reported previously from the country. For Theridiidae, the genus *Theridula* Emerton

1882 and the species *Asagena meridionalis* Kulczyński 1894 (Figure 3), *Theridion boesenbergi* Strand 1904 (Figure 4) and

Theridula gonygaster (Simon, 1873) (Figure 5) are reported for the first time from Turkey.

The current study provides the first detailed report on the spider richness of Sinop province. With the ecology and diversity of the spider fauna of the Black Sea

Region being so poorly known, each research effort contributes to our understanding of the geographical distribution of spider species. This study presents new distribution records for 192 species and indicates that spider diversity in Sinop province may be greater.

Figure 3. *Asagena meridionalis* Kulczyński 1894, male, pedipalp, ventral view. Scale bar=1mm.

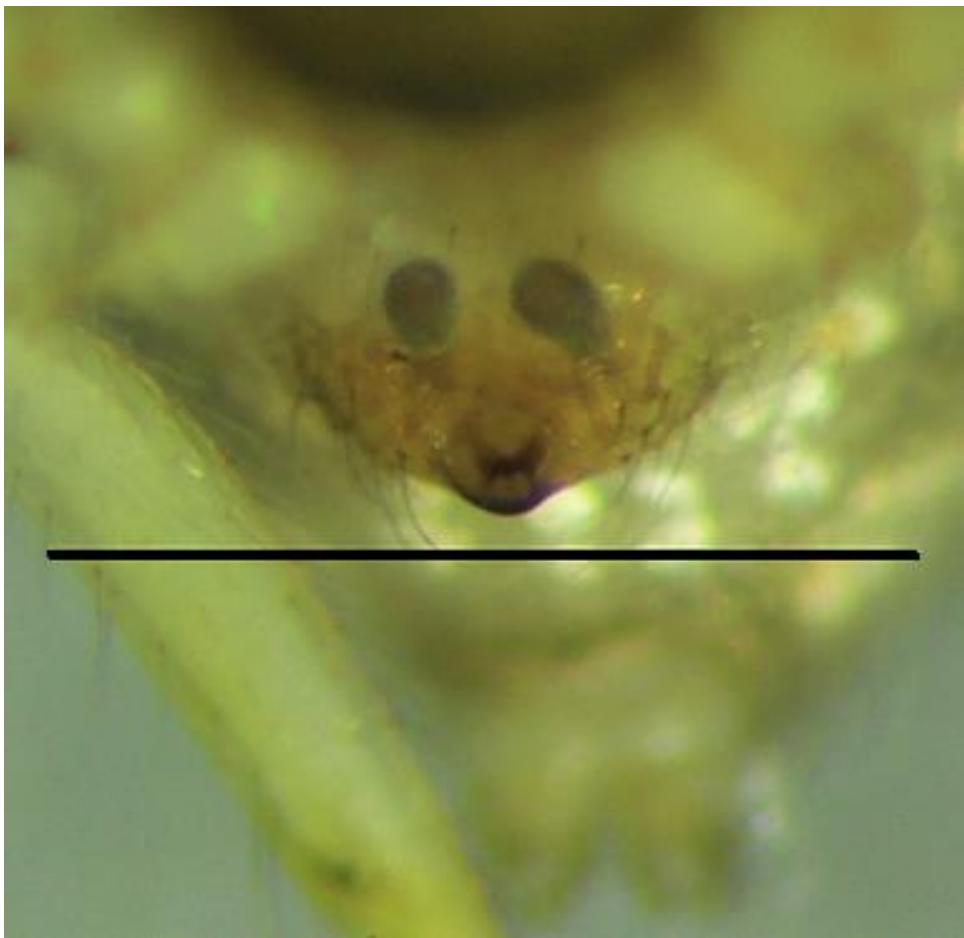

Figure 4. *Theridion boesenbergi* Strand 1904, female, ventral view of epigyne. Scale bar=1mm.

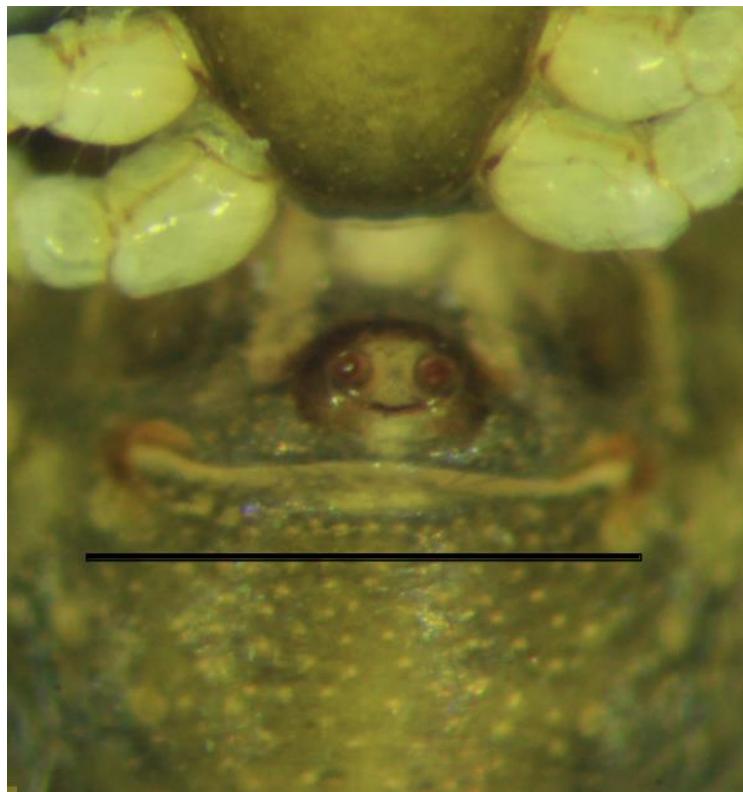

Figure 5. *Theridula gonygaster* (Simon 1873), female, ventral view of epigyne. Scale bar=1mm.
