ABSTRACT

Objectives: The purpose of this study was to investigate relation between mean platelet volume, platelet distribution width, platelet-to-lymphocyte ratio, neutrophil-to-lymphocyte ratio and vestibular migraine.

Methods: This study was planned in prospective manner and conducted in Ankara Polatlı State Hospital between April 2017 and May 2018. Thirty patients diagnosed with vestibular migraine and thirty healthy, age and sex-matched subjects were enrolled to the study. Mean platelet volume, platelet distribution width, platelet count, neutrophil count and lymphocyte count in blood samples were measured.

Results: The mean age of the patients with vestibular migraine was 39.90 ± 7.16 and the study group consisted of 11 males and 19 females. The mean platelet volume and platelet distribution width values in patients with vestibular migraine were significantly higher than the control group (p < 0.001). There were no difference on mean neutrophil/lymphocyte ratio and platelet/lymphocyte ratio values between patient group and control group.

Conclusions: We found a positive relation of increased levels of mean platelet volume and platelet distribution width with vestibular migraine. Higher mean platelet volume is associated with atherosclerosis and thromboembolism. Vascular pathologies are blamed for both headache syndromes like migraine and vertiginous syndromes. This theory supports our study but pathophysiological mechanism is not clear.

Keywords: Hematologic parameters, mean platelet volume, neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio, vestibular migraine

Vestibular migraine is an important clinical syndrome characterised by migraine type headaches accompanied with vertigo. Relation between migraine and vertigo is a complex issue and not well understood. Migraine and vertigo are common problems and a patient may have both of them by chance [1]. Thirty eight percent of migraine patients have vertigo [2-3]. Also many vertiginous pathologies are associated with migraine epidemiologically. Benign paroxysmal positional vertigo, Meniere disease, motion sickness and cerebellar disorders are associated with migraine [1]. So differentiation of vestibular migraine from these pathologies is a clinical challenge. Vestibular migraine is one of the frequent causes of both headache and ver-
Migraine prevalence is 16% and vertigo prevalence is 7% [1]. According to these values expected comorbidity of vertigo and migraine is 1.1% but Neuhauser et al. [4] showed vestibular migraine prevalence as 3.2%. In the view of such information many authors think vestibular migraine as a specific clinical entity rather than coincidental coexistence of vertigo and migraine.

Diagnosis of vestibular migraine is a challenge because pathophysiology is not well understood and there is no specific examination finding, biological marker or laboratory test [2]. Detailed and careful history is important and high index of suspicion is needed for clinician. Because of difficulties about diagnosis important part of patients are misdiagnosed [3].

Mean platelet volume (MPV) is average size of platelets and included in complete blood count. MPV gives information about platelet production rate. If platelet production accelerates in bone marrow MPV gets higher. Enlarged platelets have higher activity and produce vasoactive substances, so high MPV levels are associated with vasospasm and thrombosis [5]. Increased levels of MPV, Platelet Distribution Width (PDW), Platelet-to-Lymphocyte Ratio (PLR) and Neutrophil-to-Lymphocyte Ratio (NLR) are also associated with inflammatory pathologies and vascular pathologies such as atherosclerosis, thromboembolism [6].

There are many theories for explanation of pathophysiology of vestibular migraine. One of these theories is reversible vasospasm of the internal auditory artery or its branches. This vasospasm causes the ischemia of the labyrinth and then resulting in cochleovestibular dysfunction and vertigo experienced in vestibular migraine [7-9].

**METHODS**

This study was approved by the local ethics committee for non-invasive research and conforms to the principles of the Declaration of Helsinki. Written informed consent was obtained from all patients at the beginning of the study.

This study was planned in prospective manner and conducted in Ankara Polatlı State Hospital between April 2017 and May 2018. Thirty patients diagnosed with definite vestibular migraine according to the modified Neuhauser criteria by Lempert et al. [10] (Table 1) and thirty healthy, age and sex-matched subjects were enrolled to the study. Patients were diagnosed with vestibular migraine by neurology specialist and referred to otolaryngology clinic. All patients underwent a detailed otolaryngologic and neurologic examination. Brain and ear magnetic resonance imaging with using gadolinium as a contrast medium were obtained from all patients.

Patients were excluded from the study if they had

**Biochemical analyses**

MPV, PDW, platelet count, neutrophil count and lymphocyte count in blood samples were measured. Venous blood samples were obtained from antecubital vein at the time of vertigo attack and collected into tubes containing ethylenediaminetetraacetic acid (EDTA) at 9 am. following an overnight fast. To avoid platelet swelling measurements were done shorter than 30 minutes after sampling. An automated blood cell counter was used for these measurements (Horiba ABX Pentra DX 120).

**Statistical Analysis**

Continuous data were summarized as mean±standard deviation, and categorical data were as frequency and percentage. Independent sample t test was used to compare groups for continuous variables. Relation between categorical variables were analyzed by Chi-Square test. Statistical analyses were done with SPSS v.22.0 for Windows statistical package, and statistical significance level was considered as 0.05.

**RESULTS**

The mean age of the patients with vestibular migraine were 39.90 ± 7.16 years and 37.93 ± 7.62 years for the control group. The study group consisted of 11 males and 19 females and the control group consisted of 17 males and 13 females. There was no significant difference between age or gender in two $p = 0.307$ and $p = 0.121$, respectively) (Table 2).

The mean MPV values were 9.93 ± 0.68 fl in vestibular migraine patients and 8.24 ± 0.75 fl in the control group. The mean MPV values in patients with vestibular migraine were significantly higher than the

DISCUSSION

Pathogenesis of vestibular migraine is not well understood but there are various etiopathogenetic theories. According to cortical spreading theory cortical depolarisation wave produce vertigo [8]. Some neuropeptides are released asymmetrically and influence vestibular centers. This neuropeptid stimulation may cause vertigo at the time of migraine attack [11]. Another explanation is based on internal auditory artery spasm –may also be caused by serotonin- at the time migraine attack [7-9].

MPV and platelet count are calculated in complete blood count test routinely and MPV is unnoticed by the clinicians most of the time. MPV and platelet count levels give information about vasospasm and thrombotic function [6]. Main finding of our study was that MPV levels were significantly higher in vestibular migrainepatients than the control group.

Relation of MPV and migraine or other headache syndromes is not investigated yet and there is only single study in literature which investigated possible relation of MPV and vertigo. Celikbilek et al. [12] showed MPV levels significantly higher in benign paroxysmal vertigo patients than in controls.

Some authors studied MPV values in patients with inner ear diseases and showed controversial results. Kemal et al. [13] and Sarıkaya et al. [14] reported that MPV values were significantly higher in tinnitus patients than the control group. But Beyan and Beyan [15] reported that there was no relation between high levels of MPV values with tinnitus. Recent study by
Ulusoy et al. [16] showed that MPV values were significantly higher in tinnitus patients than the control group. MPV values were studied also in sudden sensorineural hearing loss (SSHL) patients and results were controversial like tinnitus patients. Ulu et al. [17] and Sagit et al. [18] found high levels of MPV were associated with SSHL significantly. Durmus et al. [19] also reported that MPV values were significantly higher in SSHL patients than the control group [19]. In other two studies by Karli et al. [20] and Kum et al. [21] mean MPV values of SSHL patients were higher than the control group but differences were not significant. Ozturk et al. [22] also found no difference between SSHL and control group MPV values.

This is the first study which investigates relation of mean platelet volume with vestibular migraine. In our study we found a positive relation of increased levels of MPV with vestibular migraine. But mechanism of this positive relation is not clear. We know that higher MPV is associated with vasospasm and thromboembolism [23]. Vascular pathologies are blamed for both headache syndromes like migraine and vertiginous syndromes. This theory supports our study but pathophysiological mechanism is not understood yet.

CONCLUSION

MPV can be considered as a practical and valuable parameter for assessment of vestibular migraine. And further studies are needed for explanation of relation between MPV values and vestibular migraine.

Conflict of interest

The authors disclosed no conflict of interest during the preparation or publication of this manuscript.

Financing

The authors disclosed that they did not receive any grant during conduction or writing of this study.
