Introduction

Sharp objects of metal and glass nature may cause penetrating injuries to the chest wall. These injuries may cause potential life threatening complications such as pneumothorax, hemothorax, hemoptysis attributable to pleura and lung parenchymal injuries. Sometimes the material that causes the penetrating thoracic trauma may remain in the thorax as a foreign body and cause chronic complications which may lead to possible morbidity and mortality. A case of 12 year old male patient who had a glass foreign body chipped through the left 11th rib who was promptly diagnosed and treated with surgery and recovered without any complication is presented in this report.

Case Report

A 12 year old male patient admitted to our hospital’s emergency department with penetrating wound in the back region. His medical history revealed that a glass door dropped onto him and broken into pieces. Past medical history revealed no prescribed drug use, no chronic illnesses and no allergies. Initial physical examination revealed a blood pressure of 128/79 mm Hg, heart rate of 101/min, fever of 36.3 °C. A 2 cm wide skin laceration on the intersection of 11th rib and mid-scapular line was found upon inspection. Case’s lung auscultation was normal. It was a wedge shaped piece of glass measuring about 3.5 cm of length (Figure 1a). A wedge shaped foreign body was identified on the left side with chest x ray (Figure 1b). No parenchymal injury such as hemothorax or pneumothorax was found. A thoracic CT was performed in order to identify the exact location of the foreign body. The foreign body was found at 11th intercostal space (ICS) at its intersection with the mid-scapular line (Figure 1c). Pleural and parenchymal injury was not detected. The foreign body was removed under general anesthesia. Additional exploration revealed that the foreign body struck the left 11th rib first and chipped its inferior end millimetrically and stopped at the 11th ICS without penetrating the parietal pleura. Patient was discharged at the first postoperative day without any complications. His follow up examinations in our outpatient clinics revealed no abnormalities.

Discussion

Penetrating trauma of thorax accounts for nearly 30% of all thoracic trauma cases. Penetrating injuries to the thorax with foreign bodies have been reported to cause lung parenchyma, aorta and heart and thus cause hemo-pneumothorax, hemoptysis and cardiac tamponade. Acute pen-
Some penetrating wounds may carry retained foreign bodies in the thoracic region such as broken glass, shrapnel, bullets, bone and cloth fragments\(^6\). These foreign bodies that are missed may remain dormant for a period of time or migrate through the tissues causing additional late onset injuries. Because of complications that may lead to possible morbidity and mortality such as hemo-pneumothorax, hemoptysis and pyogenic infections, these retained materials generally require immediate surgical removal at the time of diagnosis\(^5\),\(^6\). Careful history, thorough physical examination and radiological studies such as chest x-ray and thoracic computerized tomography have been advocated in the diagnosis of retained foreign bodies in the thoracic region\(^7\).

We believe that these entities should be utilized in a complementary fashion; history may yield information about the nature of the foreign body, inspection during the physical examination and the radiological studies may reveal the injuries and any possible foreign body. Despite all efforts, there are numerous cases of chronic foreign body retention in the thorax with high morbidity rates\(^1\). We could identify the foreign body in our patient with careful physical examination and radiological studies; and treated our patient with a prompt surgical removal of the object. Thus prevented possible life-threatening complications such as pneumothorax, hemothorax, hemoptysis and infections were prevented.

In conclusion, we believe that all penetrating thoracic trauma should be physically examined carefully and appropriate radiological studies should be undertaken in order to identify any possible retained foreign body. If any foreign body is found in the thoracic wall, immediate surgical removal should be performed in order to prevent any further damage to thoracic viscera, thus preventing possible life-threatening complications in the pediatric population.
