Delphinium species are well-known toxic plants with their diterpenoid alkaloid contents. There has been no previous investigation on the cytotoxicity of Delphinium formosum Boiss. & Huet. The extracts of the different parts of D. formosum, an endemic species in Turkey, were investigated for their cytotoxic activity against the human liver carcinoma cell line (HepG2) and primary human umbilical vein endothelial cells (HUVEC). The cytotoxic effects of twelve extracts and subfractions were determined against HepG2 cells using MTT assay. The only active extract was applied to the HUVEC as a model for healthy cells. Only one of the alkaloid-containing extracts from the aerial parts was toxic (IC50 = 244.9 μg/mL against HepG2 and 144.4 μg/mL against HUVEC), while the root extracts were inactive. The results were improbable although it's predicted secondary metabolites, such as diterpene alkaloids (methyllycaconitine, browniine, lycocotnine, avardharidine, antranoyllycocotnine, delsemine A/B and lycocotnine). Based on previous studies in literature, the cytotoxic plants were also expected to exhibit insecticidal activity. Therefore, the cytotoxic extract of D. formosum was examined for its adulticidal and larvicidal activity against the yellow fever, dengue fevers and Zika virus vector Aedes aegypti L.
Keywords: *Delphinium formosum*, cytotoxic activity, HepG2, HUVEC, natural insecticidal, *Aedes aegypti*.
1. Introduction

The Delphinium L. genus (Ranunculaceae), almost 300 species worldwide, consists of 29 species in Turkey (17 endemic to Anatolia). Their usages have a long history of medicinal use. Dioscorides mentioned its use against lice and scorpions. The powders of D. staphisagria L. and D. peregrinum L. were used against lice by British army in the battle of Waterloo. The dried and mature seeds of D. staphisagria, known as “kokarot, kokarotu, müzüdek, mevezek, mevzek”, were used as emetic, purgative and sedative (in the treatment of rabies, tetanus, and epilepsy) in traditional Turkish medicine. The usage was left aside due to their high toxicity. Despite their toxicity, their external applications (as ointment, powder form or infusion (1-3%), to the body or on the head) were observed also, especially for their insect repellent activity. The seeds of D. ajacis L (Syn: Consolida orientalis (Gay) Schröd.) and D. consolida L. (Syn: Consolida regalis S.F. Gray subsp. regalis) are antiparasitic (Ulubelen et al. 2001; Baytop 1999; Hiller and Melzig 2006).

Vector-borne diseases cause epidemics, leading to serious human health problems. Aedes aegypti L. (Culicidae), one of these vectors, transmits viruses like Dengue, Yellow fever, Zika, and Chikungunya. According to WHO, yellow fever is an acute viral haemorrhagic disease transmitted by infected mosquitoes and dengue is a mosquito-borne viral infection, which is a cause of flu-like illness, and evolves on occasion into a lethal complication. WHO also emphasized that, the symptoms of the infection of Zika virus, transmitted primarily by Aedes mosquitoes, are skin rash, mild fever, muscle and joint pain, headache, conjunctivitis or malaise, and is also a cause of Guillain-Barré syndrome and microcephaly (Masi et al. 2017; WHO February 2018; WHO May 2018; WHO April 2019). Many interventions are conducted to prevent these diseases and one of them is integrated mosquito control, including implementation of personal protection, destruction and reduction of its habitats, and insecticidal treatment regimens against adult and larval mosquitoes for the reduction of the virus spread. Reducing the amount of synthetic insecticides or
pesticides applied, is preferred because of their undesirable and toxic effects. Frequent chemical intervention can also cause the development of insecticide resistance (Tabanca et al. 2013a; Masi et al. 2016). Therefore, an increasing number of plant-based extracts, essential oils or phytochemicals are being investigated with the aim of determining an effective agent against Ae. Aegypti (Tabanca et al. 2018, 2016a, 2016b; Stappen et al. 2018; Chantawee and Soonwera 2018; Carroll et al. 2017; Dias et al. 2017; Masi et al. 2016; Cantrell et al. 2016; Reegan et al. 2015; Tabanca et al. 2013a, b; Kumar et al. 2012; Liu et al. 2012; Maheswaran and Ignacimuthu 2012; Pitarokili et al. 2011; Kamaraj et al. 2010).

The alkaloids, one of the most remarkable group of natural products in these plants, have a wide variety of biological activities are alkaloids. The structures of over hundred alkaloids have been identified; many of them have elicited expected anticancer activity (Lu et al. 2012). In addition to the studies on cytotoxic and anticancer effects (Liu et al. 2017; Nugroho et al. 2015; Chanakul et al. 2011), several investigations into insecticidal activities have been published (Bandara et al. 2000; Garcez et al. 2009; Liu et al. 2012; Masi et al. 2017). The diterpene and norditerpene alkaloids have also shown insecticidal activity (Ulubelen et al. 2001; Kukel and Jennings 1994). Also based on previous studies in literature, the cytotoxicity and insecticidal activities are related to each other and diterpene alkloids can be protective agents for parasite control strategies (Gonzalez-Coloma et al. 2004; Reina and Gonzalez-Coloma 2007).

This preliminary study was presented to assess the cytotoxic and insecticidal potentials of extracts, obtained from Delphinium formosum Boiss. & Huet, an endemic species in Trabzon (Turkey), which has a role in traditional medicine and a cause of serious poisoning. The different extracts of its aerial parts, roots, and flowers were investigated for their cytotoxic activity against the human liver carcinoma cell line (HepG2) and primary human umbilical vein endothelial cells...
(HUVEC). The mosquitocidal activity of the cytotoxic extract against Ae. aegypti was also determined for the possibility to use its lethal potential as insect repellent.

2. Materials and Methods

2.1 Plant material

Delphinium formosum Boiss. & Huet was collected from Koprubasi-Trabzon and Macka-Trabzon, in August 2011 and July 2012. The voucher specimen has been deposited in the Herbarium of the Faculty of Pharmacy, Istanbul University (ISTE 102747; 98086).

2.2 Extraction procedure

Dried and powdered roots, collected in the first year, were percolated with EtOH in four portions (10 L, 3 L, 2 L, 5 L) and each portion was evaporated to dryness at 40°C in vacuo (DW1, DW2, DW3 and DW4). The residues of the portions (DW1 and DW2) were acidified to pH1 by 200-300 mL 0.5 N H₂SO₄ and extracted with CHCl₃. These CHCl₃ extracts were evaporated to dryness (DW1A1K and DW2A1K). The acid solutions were basified with 5% NaOH to pH10 and extracted a second time with CHCl₃. The extracts were evaporated to dryness and named as DW1A2K and DW2A2K (Figure 1).

Dried and powdered aerial parts, flowers and roots, collected next year, were percolated with EtOH in one portion and evaporated to dryness at 40°C in vacuo. The same process was applied. Two different chloroform extracts of each part (HA1K, HA2K, FA1K, FA2K, 2DWA1K, and 2DWA2K) were acquired (Figure 2).

2.3 Biological Assays

2.3.1 Cytotoxicity Assays

2.3.1.1 Cytotoxicity test, cell lines, culture conditions and treatments
Roswell Park Memorial Institute Medium 1640 (without glutamine; RPMI-1640) with glutamine, 10% FCS and penicillin / streptomycin mixture was used for the human liver carcinoma cells (HepG2). Primary human umbilical vein endothelial cells (HUVEC) were isolated from umbilical cords by digestion with 0.01% collagenase A solution (Roche) and grown in Endothelial Cell Growth Medium with supplement mix (Promocell; C-39215) containing 10% FCS, penicillin (100 U/mL) / streptomycin (100 mg/mL) mixture, and kanamycin (50 mg/mL). Umbilical cords were obtained with the consent of patients (permission by the local ethics committee). All cells were grown at 37°C and 5% CO₂ in a humidified cell incubator. The culture medium was changed every 2 days. Monolayer cells grown to 75–85% confluence were detached with trypsin-ethylenediamine tetraacetic acid to make single cell suspensions and the viable cells were determined using the trypan blue exclusion test and diluted with medium to give a final density of 10⁵ cells/mL. The passage number range for HepG2 cell lines was maintained between 21 and 26. The passage number for primary HUVEC cells was maintained between 3 and 5. The extracts were initially dissolved in dimethyl sulfoxide (DMSO) and the stock solution of each extract was prepared at the concentration of 20 mg/mL. Next, the stock solutions were diluted in the medium to obtain final concentrations of 10-400 μg/mL. 100 μL of cell suspension per well were seeded into 96-well plates at plating density of 10⁴ cells/well for the HepG2 cells and 2x10⁴ cells/well for HUVEC and incubated to allow for cell attachment at 37°C and 5% CO₂ for 24 h. After 24 h, the medium was aspirated, and the cells were treated with 100 μl serial concentrations of all extracts. The plates were incubated at 37°C and 5% CO₂ for 24 h. The medium without samples (negative control) and with DMSO as solvent served as controls. For each extract, all concentrations were tested n=2 or n=3 in quadruplicate. The cells in each well were quantified by MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl-tetrazolium bromide) test (Kessler et al. 2013; Diesel et al. 2011; Kiemer et al. 2002; Mosmann 1983).

2.3.1.2 Cytotoxicity studies

For MTT tests, the cells were then incubated with 150 µL MTT (0.5 mg/mL in medium) solution for 3 h. After the removal of the MTT solutions, the formed formazan crystals were solubilized in 80 µL of DMSO and then the absorbance was measured at 550 nm and at 690 nm (as control wavelength) using a microplate reader.

The cell viability in treated cells compared to that of negative control cells was calculated. Then, the half maximal inhibitory concentration (IC₅₀) was expressed as the sample concentration that caused an inhibition of 50% in cytotoxicity in the cells calculated by extrapolation. The percentage of cell viability was calculated with respect to solvent control as follows:

\[
\% \text{ Cell viability} = \frac{\text{Abs}_{\text{Compounds}}}{\text{Abs}_{\text{Solvent Control}}} \times 100
\]

The results were expressed as cell death (%) compared to the negative control.

2.3.2 Insecticidal Activity

2.3.2.1 Mosquito Colony:

*Anopheles aegypti* L. used for testing were pesticide susceptible and provided from the CMAVE insectary. The “Orlando1952” strain was collected near Orlando, Florida, USA in 1952 and has been in continuous laboratory colony for 64 years. Rearing procedures are standardized and have been described previously (Tabanca et al. 2016b).

2.3.2.2 Larvicidal Activity
Larvicidal activity testing was performed essentially as described previously (Pridgeon et al. 2008), but the assay has been modified for 96-well plates to conserve limited amount of test samples by the use of smaller volumes (Masi et al. 2017). The HA1K extract was diluted in dimethyl sulfoxide (DMSO) to make 100 μg/mL. Mortality was determined in the larval assays at four different concentrations (1.0, 0.5, 0.25, and 0.1 μg/μL) in a final volume of 200 μL of larval rearing media. For each assay, a positive control of permethrin stock and a negative control of ethanol or DMSO was included. Assays were repeated at least three times on separate days using different hatches of eggs.

2.3.2.3 Adulticidal Activity

The toxicity of HA1K extract was tested in assays against adult Aedes aegypti using cohorts of 3-6-day post-emergence females as described previously (Pridgeon et al. 2008). Mosquitoes were cold anesthetized on ice and groups of 10 females sorted into individual plastic cups. Application of 0.5 μL of the appropriate dilution of the test chemical was made by repeater pipettor (Hamilton PB600) with a 25 μL blunt tip glass syringe (Hamilton 7100 series) to at least twenty females at each dose. Permethrin mixture of 46.1% cis and 53.2% trans isomers (Chemservice, West Chester, PA) was used as a positive control and acetone was used as negative control. After treatment, mosquitoes were kept in plastic cups at 24–26 °C and 80% humidity and supplied with 10% sucrose in water for 24 h prior to recording mortality.

3. Results and Discussion

Due to the diterpenoid alkaloid content of Delphinium species, we expected distinct cytotoxic actions when testing their effect on HepG2 cells. Only one extract (HA1K) was active among them, in the studied concentration ranges. The same
extract was also examined against the HUVEC cells. The IC$_{50}$ values of HA1K against two cell types (244.9 μg/mL for HepG2 and 144.4 μg/mL for HUVEC) were similar.

The MTT assay demonstrated the effect of the extracts on the % cell viability of HepG2 and HUVEC cell lines as shown in Figure 3.

![Fig. 3. The % cell viability values of the HA1K against HepG2 and HUVEC cell lines.](image)

The HA1K extract, found cytotoxic against both cell lines, was further investigated for its insecticidal activity (Table 1). The extract was evaluated at the dose of 5 μg/mosquito and had 97% mortality against adult Ae. aegypti. The positive control permethrin at 6.33 pg/μL resulted in 53 ± 11% mortality while negative control acetone resulted in 0% mortality. In larval activity, the HA1K extract showed 80% mortality at the highest dose of 1 μg/μL against 1st instar Ae. aegypti; however, the mortality titrated off quickly at the lower doses. Negative control mortality in larvicidal assays was 0% for DMSO, and positive control permethrin resulted in 100% at the 47.4 pg/μL. Since HA1K extract produced 97% mortality against adult Ae. aegypti, isolation of the active compound/-s through bioassay-guided fractionation and its/their characterization may be promising.

This is the first investigation on the cytotoxicity and insecticidal activity of *D. formosum*. On the other hand, several studies on the cytotoxic effect of the isolated compounds from other species exist in the literature. De Inés et al. evaluated 43 norditerpenoid alkaloids from *Aconitum*, *Delphinium* and *Consolida* species for their cytotoxic effects on the tumor cell lines SkMel28 (human malignant melanoma), HeLa (human cervical adenocarcinoma), SkMel25 (human melanoma), CT26 (murine colon adenocarcinoma), and SW480 (human colon adenocarcinoma) and the non-tumor cell line CHO (Chinese hamster ovary cells). Browniine, ajadelphinine, 8-O-methylcolumbianine, dehydrotakaosamine, lycocotonine, 14-deacetyllajadine, pubescenine, 14-deacetylpubescenine, 1,14-diacetylcardiopetaline, 18-O-demethylpubescenine, delphatine and neoline showed selective cytotoxicity. The most active compound was a gadesine-type norditerpene alkaloid, dehydrotakaosamine. Its IC$_{50}$ values were detected 0.40 µg/mL against HeLa cells and 6.25 µg/mL against CT26, SW480 and SkMe125 cells. Lycocotonine was found active against CT26 and SW480 (IC$_{50}$ = 50 µg/mL), while methyllycaconitine showed an activity against CHO, CT26, SW480 and HeLa (IC$_{50}$ = 12.50 µg/mL, 12.50 µg/mL, 50 µg/mL, 50 µg/mL; respectively). All IC$_{50}$ values of browniine were more than 100 µg/mL against all cell lines, but an effect was seen by browniine against CT26 and SW480 cells (De Ines et al. 2006). In another study, from *Aconitum vulparia* isolated compounds (vulparine, finetiadine, anthranoyllycocotonine) exhibited a cell growth inhibitory activity against cervix adenocarcinoma (HeLa) and breast adenocarcinoma (MCF-7) cell lines. Finetiadine was the most cytotoxic compound at 30 µg/mL with

the 39.48 ± 3.42% on MCF-7 cell line and 25.59 ± 1.87% inhibition on HeLa cell line, while septentriodine and anthranoyllycoctonine showed also a tumour cell inhibitory activity. Septentriodine shown an activity (34.50 ± 3.72% inhibition) against MCF-7 cells only at the concentration of 30 µg/mL (Csupor et al. 2007).

In a study on *Delphinium* alkaloids to determine the inhibition of α-bungarotoxin binding to insect and rat neural membranes, 17 *Delphinium* alkaloids were tested. Among them, glaudelsine showed the highest inhibition on the insect binding site even 10x more potent than methyllycaconitine, which were known as most potent alkaloid until that date (Kukel and Jennings 1994). In another study, 29 diterpene and norditerpene alkaloids from *Delphinium, Consolida* and *Aconitum* species were investigated against *Tribolium castaenum* (Herbst.) to evaluate the repellent effects. Twenty-one alkaloids exhibited promising insect repellent activity (Ulubelen et al. 2001). The hetisine, a diterpen alkaloid, was found the most active repellency (59.12%). The compounds, delsemin-B, lycoctonine, browniine, showed also an activity against *Tribolium castaenum* (Ulubelen et al. 2001).

In a previous study on *Delphinium* from Black Sea area (Trabzon) in Turkey collected *D. formosum*, delsemine A and B, 14-demethylajacine (N-acetyldelectine), lycoctonine, anthranoyllycoctonine, delcosine, and delectine were identified from the aerial parts (Mericli et al. 1996). Additionally, lycoctonine and delsemine were isolated from *D. formosum* roots, collected in Trabzon, in a previous study (Tanker and Ozden 1975). Durust et al. (1999) isolated also some phenolic acids such as p-coumaric, p-hydroxy benzoic, caffeic, protocatechic and vanillic acids) from the flowers of *D. formosum*, collected in same region, with four different methods. In our recent study, we reinvestigated of norditerpenoid alkaloids from the *D. formosum* roots and methyllycaconitine, browniine, lycoctonine, avardharidine, antranoyllycoctonine and delsemine A/B were isolated (Sen-Utsukarci et al. 2018).

All of the aforementioned studies on the cytotoxic effects of diterpenoids and norditerpenoid alkaloids have a contribution on the cytotoxicity. The difference
of cytotoxicity of *D. formosum* (aerial parts and roots) can be explained with the diversity of secondary metabolites in the root-extracts. In the light of all, it gives the impression that the extracts may contain a different percentage of the active substances.
