ABSTRACT

Grover and Kaur [4], Haq et al. [5], Abd-Elfattah et al. [1], Jhajj et al. [6], Shabbir and Gupta [8] and Koyuncu [7] have suggested some families of estimators by using the known population proportion of elements possessing attribute in the simple random sampling and in the two phase sampling. In this paper, after adapting these families of estimators to the stratified random sampling, we have proposed a family of exponential ratio type estimators which uses the information regarding the population proportion possessing certain attribute. For the proposed family of estimators, the expressions of bias and mean square error (MSE) up to the first order approximations are derived and the optimum case of the proposed family is discussed in theory. Also an empirical study is carried out to show its properties.

Key words: Attribute, auxiliary information, efficiency, exponential ratio estimator, stratified random sampling.

1. INTRODUCTION

Grover and Kaur [4], Haq et al. [5], Abd-Elfattah et al. [1], Jhajj et al. [6], Shabbir and Gupta [8] and Koyuncu [7] suggested some estimators of population mean taking the advantage of point bi-serial correlation between the study variable and the auxiliary attribute. In simple random sampling, Bahl and Tuteja [2] introduced exponential estimators for finite population mean. Following Bahl and Tuteja [2], Singh and Vishwakarma [10] suggested exponential ratio and product estimators of population mean in double sampling. Shabbir and Gupta [9] proposed a new ratio-type exponential estimator for population variance in simple random sampling. Singh et al. [11] proposed some exponential ratio-type estimators for estimating the population mean using known values of certain population parameter(s) under simple random sampling scheme. In this paper, we proposed a family of exponential ratio type estimators for estimating the population mean using known values of two auxiliary attributes.

Assume that the population of size, \( N \), is stratified into \( L \) strata with the \( h \)-th stratum containing \( N_h \) units,
where \( h = 1, 2, \ldots, L \) such that \( \sum_{h=1}^{L} N_h = N \). A simple random sample of size \( n_h \) is drawn without replacement from the \( h \)-th stratum such that \( \sum_{h=1}^{L} n_h = n \). Let \((y_{hi}, \psi_{1hi}, \psi_{2hi})\) denote observed values of \( Y \) and auxiliary attributes \( \psi_1, \psi_2 \) on the \( i \)-th unit of the \( h \)-th stratum, respectively, where \( i = 1, 2, \ldots, N_h \) and \( h = 1, 2, \ldots, L \). Moreover, \( \psi_{hi} = \begin{cases} 1, & h \text{-th stratum } i \text{-th unit possesses the attribute } \psi_1, \\ 0, & \text{otherwise} \end{cases} \)

Supposing that \( A_{jh} = \sum_{i=1}^{n_h} \psi_{jhi} \) and
\[
a_{jh} = \sum_{i=1}^{n_h} \psi_{jhi}, \quad P_{jh} = \frac{\sum_{i=1}^{n_h} \psi_{jhi}}{N_h} = \frac{A_{jh}}{N_h}, \quad p_{jh} = \frac{\sum_{i=1}^{n_h} \psi_{jhi}}{n_h} = \frac{a_{jh}}{n_h} \quad (j = 1, 2)
\]
are the \( h \)-th proportion of units in population and sample, respectively. Let
\[
S_{jih}^2 = \frac{\sum_{i=1}^{n_h} (y_{hi} - \bar{Y}_h)^2}{n_h - 1},
\]
\[
S_{p,jh}^2 = \frac{\sum_{i=1}^{n_h} (\psi_{jhi} - p_{jh})^2}{n_h - 1}
\]
be the \( h \)-th sample variances and let \( S_{j,h}^2 = \frac{\sum_{i=1}^{N_h} (y_{hi} - \bar{Y}_h)^2}{N_h - 1} \)
be the population variances of the study variable and auxiliary attributes, respectively. Also
\[
s_{y,\psi,jh} = \frac{\sum_{i=1}^{n_h} (y_{hi} - \bar{Y}_h)(\psi_{jhi} - p_{jh})}{n_h - 1}
\]
\[
\hat{\rho}_{y,\psi,j} = \frac{s_{y,\psi,jh}}{s_{y,jh}s_{\psi,jh}} \quad (j = 1, 2)
\]
are, respectively, the \( h \)-th sample covariance and point bi serial correlation, and
\[
\hat{\rho}_{\psi,j} = \frac{s_{\psi,jh}}{s_{\psi,\psi,jh}} \quad (j = 1, 2)
\]
be the \( h \)-th sample phi-covariance and phi correlation, respectively, and let
\[
S_{\psi,\psi,jh} = \frac{\sum_{i=1}^{N_h} (\psi_{1hi} - P_{1h})(\psi_{2hi} - P_{2h})}{N_h - 1}
\]
be the \( h \)-th population phi covariance and phi correlation, respectively, between the first and the second auxiliary attributes.

To obtain the bias and \( \textit{MSE} \), let us define
\[
\xi_{0} = \left( \bar{Y}_s - \bar{Y} \right) / \bar{Y}, \quad \xi_{\psi_1} = \left( P_{1st} - P_1 \right) / P_1, \quad \xi_{\psi_2} = \left( P_{2st} - P_2 \right) / P_2 \quad \text{where} \quad \bar{Y}_s = \frac{\sum_{h=1}^{L} W_h \bar{Y}_h}{\sum_{h=1}^{L} W_h}
\]
\[
P_{1st} = \frac{\sum_{h=1}^{L} W_h P_{1h}}{\sum_{h=1}^{L} W_h} \quad \text{and} \quad P_{2st} = \frac{\sum_{h=1}^{L} W_h P_{2h}}{\sum_{h=1}^{L} W_h}
\]

Using these notations,
\[
E(\xi_{0}) = E(\xi_{\psi_1}) = E(\xi_{\psi_2}) = 0.
\]
\[ N_{rs} = \sum_{h=1}^{L} W_{h}^{*r,s} E \left[ (\bar{y}_h - \bar{y}_h)' (p_{th} - P_{th})' (p_{2h} - P_{2h})' \right] / \bar{Y}'P_i'P_2' \]  

Using (1.1), we can write

\[ E(\bar{x}_0^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h S_{yh}^2}{\bar{Y}^2} = N_{00}, \]

\[ E(\bar{x}_w^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h S_{w,h}}{P_1^2} = N_{02}, \]

\[ E(\bar{x}_w^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h S_{w,h}^2}{P_2^2} = N_{02}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{\bar{Y}P_1} = N_{10}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{\bar{Y}P_2} = N_{10}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{P_1 P_2} = N_{10}, \]

where \( \gamma_h = \frac{N_h - n_h}{N_h n_h} \).

For the one auxiliary attribute case, we can define similar expressions as

\[ N_{rs} = \sum_{h=1}^{L} W_h^{*r,s} E \left[ (\bar{y}_h - \bar{y}_h)' (p_{th} - P_{th})' (p_{2h} - P_{2h})' \right] / \bar{Y}'P_i'P_2' \]  

Using (1.2), we can write

\[ E(\bar{x}_0^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h S_{yh}^2}{\bar{Y}^2} = N_{00}, \]

\[ E(\bar{x}_w^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h S_{w,h}}{P_1^2} = N_{02}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{\bar{Y}P_1} = N_{10}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{\bar{Y}P_2} = N_{10}, \]

\[ E(\bar{x}_y^2) = \sum_{h=1}^{L} \frac{W_h^2 \gamma_h \rho_{yw,th} S_{y,h} S_{w,h}}{P_1 P_2} = N_{10}, \]

where \( \gamma_h = \frac{N_h - n_h}{N_h n_h} \).

2. ADAPTIVE ESTIMATORS

The classical ratio estimator using a single auxiliary attribute in the stratified random sampling is given by

\[ t_1 = \frac{\bar{Y}_{st} P}{P_{st}}. \]  

(2.1)

The bias and MSE of \( t_1 \), to the first order of approximation, are given by

\[ B(t_1) = \bar{Y}(N_{02} - N_{11}), \]

(2.2)

\[ \text{MSE}(t_1) = \bar{Y}^2 (N_{02} + N_{20} - 2N_{11}). \]  

(2.3)

(Cingi and Kadilar [3]). Following Jhajj et al.[6], a general combined class in the stratified random sampling is defined by

\[ \bar{y}_{g(u)} = g(\bar{Y}_{st}, u_{st}), \]  

(2.4)

where \( u_{st} = \frac{P_{st}}{P} \) and \( g(\bar{Y}_{st}, u_{st}) \) is a function of \( \bar{Y}_{st} \) and \( u_{st} \). To study the properties of \( \bar{y}_{g(u)} \) we assume following regularity conditions:

1. The point \( (\bar{Y}_{st}, u_{st}) \) assumes the value in a closed convex subset \( R_2 \) of two dimensional real space containing the point \( (\bar{Y}, 1) \).

2. The function \( g(\bar{Y}_{st}, u_{st}) \) is continuous and bounded in \( R_2 \).

3. \( g(\bar{Y}, 1) = \bar{Y} \) and \( g_0(\bar{Y}, 1) = 1 \), where \( g_0(\bar{Y}, 1) \) denotes the first order partial derivative of \( g \) with respect to \( \bar{Y}_{st} \).
The first and the second order partial derivatives of \( f(x, y) \) exist and are continuous and bounded in \( \mathbb{R}^2 \).

Expanding \( f(x, y) \) about the point \( (\bar{x}, \bar{y}) \) in a second order Taylor series and using the above regularity conditions, we have

\[
\tilde{t}_{g(st)} = \bar{y} + (y - 1)g_1 + (v - 1)^2 g_2 + (y - \bar{y})(v - 1)g_3 + (y - \bar{y})^2 g_4
\]

(2.5)

The class of estimators \( \tilde{t}_{g(st)} \), in terms of \( \xi_0 \) and \( \xi_{\psi_1} \), can be written as,

\[
\tilde{t}_{g(st)} - \bar{y} = \bar{y} \xi_0 + \bar{y} \xi_{\psi_1} g_1 + \bar{y}^2 \xi_{\psi_1} g_2 + \bar{y} \xi_0 \xi_{\psi_1} g_3 + \bar{y}^2 \xi_{\psi_1} g_4
\]

(2.6)

and the bias and the MSE of \( \tilde{t}_{g(st)} \) are, respectively, given by

\[
B(\tilde{t}_{g(st)}) = g_2 N_{02} + g_3 N_{11} + g_4 \bar{y}^2 N_{20},
\]

(2.7)

\[
\text{MSE}(\tilde{t}_{g(st)}) = \bar{y}^2 N_{20} + N_{02}^2 + 2 \bar{y} N_{11} G_1.
\]

(2.8)

By using the optimal value of \( \xi^*_1 = -\frac{N_{11}}{N_{02}} \), the minimum MSE of the estimators in the class \( \tilde{t}_{g(st)} \) is found as

\[
\bar{y}_{M(st)} \approx \bar{y}(1 + \xi_0) (d_{1st} - P d_{2st} \xi_{\psi_1}) (1 - \xi_{\psi_1} + \xi_{\psi_1}^2)
\]

(2.11)

The bias and MSE of the estimator to the first order of approximations are, respectively, given by

\[
B(\bar{y}_{M(st)}) \approx \bar{y} \left[ (d_{1st} - 1) - (P d_{2st} + d_{1st}) N_{11} + (P d_{2st} + d_{1st}) N_{02} \right]
\]

(2.12)

\[
\text{MSE}(\bar{y}_{M(st)}) \approx \bar{y}^2 \left[ 1 + d_{1st}^2 (1 + N_{20} + 3 N_{02} - 4 N_{11}) + 4 P d_{1st} d_{2st} (N_{02} - N_{11}) - 2 d_{1st} (1 + N_{02} - N_{11}) + P^2 d_{2st}^2 N_{02} + 2 P d_{2st} (N_{11} - N_{02}) \right]
\]

(2.13)

The optimum values of \( d_{1st}, d_{2st} \) and minimum MSE of \( \bar{y}_{M(st)} \) are given by

\[
d_{1st}^* = -\frac{N_{02} + N_{02}^2 - N_{11} N_{02} - 2 N_{02}^2 - 2 N_{11}^2 + 4 N_{02} N_{11}}{N_{02} + N_{20} N_{02} - N_{02}^2 - 4 N_{11}^2 + 4 N_{02} N_{11}}.
\]

(2.14)
\[
d^*_2 = \frac{N_{20}N_{20} - N_{11}N_{20} - 3N_{11}N_{02} - N_{02} + N_{02}^2 + N_{11}^2 + 2N_{11}^2}{P(N_{02} + N_{02}N_{20} - N_{02}^2 - 4N_{11}^2 + 4N_{02}N_{11})},
\]

where \( k_{2st} \) is a suitable constant, \( a_{st} \) and \( b_{st} \) are either real numbers or the functions of the known parameters for the \( h \)-th stratum of the auxiliary attribute, \( \gamma_{st} \), such as \( \gamma_{st}^1 \), \( \gamma_{st}^2 \), and \( \gamma_{st}^3 \).

Some new estimators can be generated from (3.1) for different combinations of \( k_{1st} \), \( k_{2st} \), \( \gamma_{1st} \), \( \gamma_{2st} \), \( a_{st} \), \( b_{st} \), \( c_{st} \), and \( d_{st} \).

**Case 1:** For this family of estimators firstly we consider the case of \( k_{1st} + k_{2st} = 1 \) then we can rewrite (3.1) in terms of \( \xi_{1i} \) as

\[
\bar{y}_N - \bar{y} \equiv \bar{y}\left\{k_{1st} \left( a_{st}\xi_{0_{st}} + \frac{a_{st}(a_{st} + 2b_{st})}{2!}\xi_{0_{st}} + \gamma_{1st}(\gamma_{1st} + 1)\xi_{0_{st}}^2 - \gamma_{1st}\xi_{1_{st}}\right) + k_{2st} \left( c_{st}\xi_{0_{st}} + \frac{c_{st}(c_{st} - 2d_{st})}{2!}\xi_{0_{st}}^2 - \gamma_{2st}\xi_{0_{st}}\right)\right\}
\]

The bias and MSE of the estimator in (3.1), to the first-order of approximation, are, respectively, given by

\[
B(\bar{y}_N) \equiv \bar{y}\left\{k_{1st} \left( a_{st}\xi_{0_{st}} + \frac{a_{st}(a_{st} + 2b_{st})}{2!}\xi_{0_{st}} + \gamma_{1st}(\gamma_{1st} + 1)\xi_{0_{st}}^2 - \gamma_{1st}\xi_{1_{st}}\right) N_{020} + (a_{st} - \gamma_{1st})N_{110}\right\}
\]

\[
+ k_{2st} \left( c_{st}\xi_{0_{st}} + \frac{c_{st}(c_{st} - 2d_{st})}{2!}\xi_{0_{st}}^2 - \gamma_{2st}\xi_{0_{st}}\right) N_{002} + (c_{st} - \gamma_{2st})N_{101}\right\}
\]
\[
\text{MSE}(\bar{y}_N) \cong \bar{y}^2 \left\{ N_{200} + t_{1st}^2 N_{020} + t_{2st}^2 N_{002} + 2t_{1st} N_{110} + 2t_{2st} N_{101} + 2t_{1st} t_{2st} N_{011} \right\}
\]  
(3.4)

where \( t_{1st} = K_{1st} (a_{st} - \gamma_{1st}) \) and \( t_{2st} = K_{2st} (c_{st} - \gamma_{2st}) \).

From (3.4), we get the optimum values of \( t_{1st} \) and \( t_{2st} \), given by

\[
\text{Substituting the optimum values of } t_{1st} \text{ and } t_{2st}, \text{ we get minimum } \text{MSE} \text{ of } \bar{y}_N, \text{ as given by}
\]

\[
\text{MSE}_{\text{min}}(\bar{y}_N) \cong \bar{y}^2 \left\{ N_{200} - \frac{N_{020} N_{110}^2 + N_{101}^2 N_{002} - 2N_{110} N_{011} N_{101}}{N_{020} - N_{002}^2} \right\}
\]  
(3.6)

**Case 2:** Now we consider the case of \( K_{1st} + K_{2st} \neq 1 \). Some new estimators which are generated from (3.1) for different combinations of \( K_{1st}, K_{2st}, \gamma_{1st}, \gamma_{2st}, a_{st}, b_{st}, c_{st} \), and \( d_{st} \) are given in Table 1. Then, we can rewrite (3.1) in terms of \( \xi_{i}, \ i = 0, \psi_{1}, \psi_{2} \) as

\[
\bar{y}_N^* - \bar{y} \cong \bar{y} \left\{ K_{1st} \left( 1 + a_{st} \xi_{\psi_{1}} + \frac{a_{st}(a_{st} - 2b_{st})}{2!} \xi_{\psi_{1}}^2 - \gamma_{1st} \xi_{\psi_{1}} - \gamma_{1st} a_{st} \xi_{\psi_{1}}^2, \right.ight.
\]

\[
\left. \left. + \gamma_{1st} \left( \gamma_{1st} + 1 \right) \xi_{\psi_{1}}^2 \frac{2}{2!} \xi_{\psi_{1}} + \xi_{0} + a_{st} \xi_{0} \xi_{\psi_{1}} - \gamma_{1st} \xi_{0} \xi_{\psi_{1}} \right) + K_{2st} \left( 1 + c_{st} \xi_{\psi_{2}} + \frac{c_{st}(c_{st} - 2d_{st})}{2!} \xi_{\psi_{2}}^2 - \gamma_{2st} \xi_{\psi_{2}} - \gamma_{2st} c_{st} \xi_{\psi_{2}}^2, \right.ight.
\]

\[
\left. \left. + \gamma_{2st} \left( \gamma_{2st} + 1 \right) \xi_{\psi_{2}}^2 \frac{2}{2!} \xi_{\psi_{2}} + \xi_{0} + c_{st} \xi_{0} \xi_{\psi_{2}} - \gamma_{2st} \xi_{0} \xi_{\psi_{2}} \right) - 1 \right\}
\]  
(3.7)

The bias and MSE of the estimator in (3.1), to the first-order of approximation, are, respectively, given by

\[
B(\bar{y}_N^*) \cong \bar{y} \left\{ K_{1st} \left( 1 + \left( a_{st}(a_{st} - 2b_{st}) \right) \frac{2!}{2} \xi_{\psi_{1}} + \gamma_{1st} \left( \gamma_{1st} + 1 \right) \xi_{\psi_{1}} + \gamma_{1st} a_{st} \xi_{\psi_{1}}^2, \right. \right.
\]

\[
\left. \left. + K_{2st} \left( 1 + \left( c_{st}(c_{st} - 2d_{st}) \right) \frac{2!}{2} \xi_{\psi_{2}} + \gamma_{2st} \left( \gamma_{2st} + 1 \right) \xi_{\psi_{2}} + \gamma_{2st} c_{st} \xi_{\psi_{2}}^2, \right. \right.
\]

\[
\left. \left. + \gamma_{2st} a_{st} \xi_{\psi_{2}} + \gamma_{2st} c_{st} \xi_{\psi_{2}} - \gamma_{2st} a_{st} \xi_{\psi_{2}}^2, \right) + \gamma_{2st} \xi_{\psi_{2}}^2 \frac{2}{2!} \xi_{\psi_{2}} + \xi_{0} + c_{st} \xi_{0} \xi_{\psi_{2}} - \gamma_{2st} \xi_{0} \xi_{\psi_{2}} \right) - 1 \right\}
\]  
(3.8)

\[
\text{MSE}(\bar{y}_N^*) \cong \bar{y}^2 \left\{ 1 + K_{1st}^2 A + K_{2st}^2 B + 2K_{1st} K_{2st} C - 2K_{1st} D - 2K_{2st} E \right\}
\]  
(3.9)

where

\[
A = 1 + \left( 2a_{st}^2 + 2\gamma_{1st}^2 - 2a_{st} b_{st} - 4\gamma_{1st} a_{st} + \gamma_{1st} \right) N_{020} + N_{200} + 4(a_{st} - \gamma_{1st}) N_{110}
\]

\[
B = 1 + \left( 2c_{st}^2 + 2\gamma_{2st}^2 - 2c_{st} d_{st} - 4\gamma_{2st} c_{st} + \gamma_{2st} \right) N_{002} + N_{200} + 4(c_{st} - \gamma_{2st}) N_{101}
\]
From (3.9), we get the optimum values of $K_{1st}$ and $K_{2st}$, given by

$$C = 1 + \left\{ \frac{a_{st}(a_{st} - 2b_{st})}{2} - \gamma_{1st}a_{st} + \frac{\gamma_{1st}(\gamma_{1st} + 1)}{2} \right\} N_{020} + \left( a_{st} - \gamma_{1st} \right) N_{110}$$

$$+ \left( a_{st}c_{st} - \gamma_{1st}c_{st} - \gamma_{2st}a_{st} + \gamma_{2st}\gamma_{1st} \right) N_{011} + 2\left( c_{st} - \gamma_{2st} \right) N_{101}$$

$$+ \left\{ c_{st}(c_{st} - 2d_{st}) - \gamma_{2st}c_{st} + \frac{\gamma_{2st}(\gamma_{2st} + 1)}{2} \right\} N_{002} + N_{200}$$

$$D = 1 + \left\{ \frac{a_{st}(a_{st} - 2b_{st})}{2} - \gamma_{1st}a_{st} + \frac{\gamma_{1st}(\gamma_{1st} + 1)}{2} \right\} N_{020} + \left( a_{st} - \gamma_{1st} \right) N_{110}$$

$$E = 1 + \left\{ \frac{c_{st}(c_{st} - 2d_{st})}{2} - \gamma_{2st}c_{st} + \frac{\gamma_{2st}(\gamma_{2st} + 1)}{2} \right\} N_{002} + \left( c_{st} - \gamma_{2st} \right) N_{101}$$

The $\bar{Y}_N$-family of estimators is more efficient than $\bar{t}_1$ if

$$MSE_{min}(\bar{Y}_N) < MSE(\bar{t}_1).$$

$$MSE_{min}(\bar{Y}_N) < MSE(\tilde{t}_{g(st)}).$$

$$MSE_{min}(\bar{Y}_N) < MSE(\tilde{t}_{M(st)}).$$

When the condition (4.1) is satisfied, we can infer that the $\bar{Y}_N$ family is more efficient than $\bar{t}_1$ estimator.

The $\bar{Y}_N$-family of estimators is more efficient than $\tilde{t}_{g(st)}$ if

$$MSE_{min}(\bar{Y}_N) < MSE_{min}(\tilde{t}_{g(st)}).$$

The $\bar{Y}_N$-family of estimators is more efficient than $\bar{Y}_M(st)$ if

$$MSE_{min}(\bar{Y}_N) < MSE_{min}(\bar{Y}_M(st)).$$

$$\frac{N_{11}^2}{N_{02}} - \frac{N_{020}N_{101}^2 + N_{110}^2}{N_{020}N_{002} - N_{011}^2} < 0 . (4.2)$$

$$N_{200} - \frac{N_{020}N_{101}^2 + N_{110}^2}{N_{020}N_{002} - N_{011}^2} \times \left\{ \begin{array}{l}
N_{020} - \frac{N_{020}N_{101}^2 + N_{110}^2}{N_{020}N_{002} - N_{011}^2} \\
2N_{011}N_{110}N_{20} - 3N_{11}^2 + N_{20}^2N_{02} + N_{20}N_{02}^2 + N_{20}N_{02}^2 - 2N_{02}N_{11}N_{20}
\end{array} \right\} < 1 . (4.3)$$

$$\frac{N_{02}^2}{N_{02}} - \frac{N_{020}N_{101}^2}{N_{020}N_{002} - N_{011}^2} - 4N_{11}^2 + 4N_{02}N_{02} - 4N_{11}^2 + 4N_{02}N_{02}$$
When the condition (4.3) is satisfied, we can infer that the $\tilde{\mathbf{Y}}_N$ family is more efficient than $\mathbf{Y}_{M(st)}$ estimator.

The $\tilde{\mathbf{Y}}_N^*$ family of estimators is more efficient than $\mathbf{t}_1$ estimator.

$$\text{MSE}_{\min}(\tilde{\mathbf{Y}}_N^*) < \text{MSE}(\mathbf{t}_1),$$

$$1 - N_{st} - N_{st1} + 2N_{11} - \frac{B^2 + A^2 - 2CED}{AB - C^2} < 0 \quad (4.4)$$

When the condition (4.4) is satisfied, we can infer that the $\tilde{\mathbf{Y}}_N^*$ family is more efficient than $\mathbf{t}_1$ estimator.

The $\mathbf{Y}_N^*$ family of estimators is more efficient than $\mathbf{t}_{g(st)}$ if

$$\text{MSE}_{\min}(\mathbf{Y}_N^*) < \text{MSE}_{\min}(\mathbf{t}_{g(st)}),$$

$$1 - \frac{BD^2 + AE^2 - 2CED}{AB - C^2} < 0 \quad (4.5)$$

When the condition (4.5) is satisfied, we can infer that the $\mathbf{Y}_N^*$ family is more efficient than $\mathbf{t}_{g(st)}$ estimator.

When the condition (4.6) is satisfied, we can infer that the $\mathbf{Y}_N^*$ family is more efficient than $\mathbf{Y}_{M(st)}$ estimator.

$$\text{MSE}_{\min}(\mathbf{Y}_N^*) < \text{MSE}_{\min}(\mathbf{Y}_{M(st)}),$$

$$\frac{N_{02} - N_{02}^2 + 4N_{11}N_{02} - 3N_{11}^2 + N_{20}N_{02}^2 + N_{20}N_{11}^2 - 2N_{02}N_{11}N_{20} - \frac{BD^2 + AE^2 - 2CED}{AB - C^2}}{N_{02} + N_{20}N_{02} - N_{02}^2 - 4N_{11}^2 + 4N_{02}N_{11}} < 0 \quad (4.6)$$

5. NUMERICAL EXAMPLE

In this study we use the data of apple production amount in 1999 as study variable, number of apple trees less than 20,000 in 1999 and apple production amount less than 1000 tons in 1998 as auxiliary attributes in 854 villages of Turkey (Source: Institute of Statistics, Republic of Turkey).

Firstly, we have stratified the data by regions of Turkey (as 1:Marmara 2:Agean 3:Mediterranean 4:Central Anatolia 5:Black Sea 6:East and Southeast Anatolia) and from each stratum; we have randomly selected the samples whose sizes are computed by using Neyman allocation method. The summary of the data is given in Table 2.

The $\text{MSE}$ values of the adapted estimators ($\mathbf{t}_1$, $\mathbf{t}_{g(st)}$), $\mathbf{Y}_{M(st)}$ and suggested estimators ($\mathbf{Y}_N$, $\mathbf{Y}_N^*$) have been obtained using (2.3), (2.9), (2.16), (3.6), and (3.11), respectively. These values are given in Table 3.

When we examine Table 3, we observe that the $\mathbf{Y}_{N1}$, $\mathbf{Y}_{N9}$, $\mathbf{Y}_{N13}$ estimators have the smallest $\text{MSE}$ values and are more efficient than adapted and other suggested estimators. From this result, we can conclude that using suitable known parameters of auxiliary attributes in estimators give more efficient results.

We also compute the percent relative efficiency (PRE) using the following expression

$$\text{PRE} = \frac{\text{MSE}(\mathbf{t}_{1})}{\text{MSE}(\mathbf{\alpha})} \times 100$$

where $\mathbf{\alpha} = \mathbf{Y}_{N1}^*, \mathbf{Y}_{N2}^*, \ldots, \mathbf{Y}_{N13}^*, \mathbf{Y}_{M(st)}^*, \mathbf{Y}_N^*, \mathbf{t}_{g(st)}^*$.

When we examine Table 3, all suggested estimators are more efficient than classical ratio estimator. From Table 3 we can see that $\bar{Y}_N$ family is more efficient than $t_1$; $\bar{Y}_N$ family is more efficient than $\bar{t}_{(s1)}$ estimator. We can infer that conditions given in (4.1) and (4.2) are satisfied. But $\bar{Y}_N$ family isn’t more efficient than $\bar{Y}_{M(s)}$ estimator. So we can say that the condition in (4.3) isn’t satisfied for this data set.

All member of $\bar{Y}_N$ family are more efficient than $t_1$ estimator and the condition in (4.4) is satisfied. Member of $\bar{Y}_N$ such as $\bar{Y}_{N1}^*$, $\bar{Y}_{N2}^*$, $\bar{Y}_{N4}^*$, $\bar{Y}_{N5}^*$, $\bar{Y}_{N7}^*$, $\bar{Y}_{N8}^*$, $\bar{Y}_{N9}^*$, $\bar{Y}_{N10}^*$, $\bar{Y}_{N12}^*$, $\bar{Y}_{N13}^*$, $\bar{Y}_{N14}^*$ and $\bar{Y}_{N16}^*$ are more efficient than $\bar{t}_{(s1)}$ estimator and the condition in (4.5) is satisfied for these estimators. Member of $\bar{Y}_N$ such as $\bar{Y}_{N3}^*$, $\bar{Y}_{N6}^*$, $\bar{Y}_{N11}^*$ and $\bar{Y}_{N15}^*$ aren’t more efficient than $\bar{t}_{(s1)}$ and condition in (4.5) isn’t satisfied for these estimators. Member of $\bar{Y}_N$ such as $\bar{Y}_{N1}^*$, $\bar{Y}_{N2}^*$, $\bar{Y}_{N4}^*$, $\bar{Y}_{N5}^*$, $\bar{Y}_{N8}^*$, $\bar{Y}_{N9}^*$, $\bar{Y}_{N10}^*$, $\bar{Y}_{N12}^*$, $\bar{Y}_{N13}^*$, $\bar{Y}_{N14}^*$, $\bar{Y}_{N16}^*$ are more efficient than $\bar{Y}_{M(s)}$ and the condition in (4.6) is satisfied for these estimators. But member of $\bar{Y}_N$ such as $\bar{Y}_{N3}^*$, $\bar{Y}_{N6}^*$, $\bar{Y}_{N7}^*$, $\bar{Y}_{N11}^*$ and $\bar{Y}_{N15}^*$ aren’t more efficient than $\bar{Y}_{M(s)}$ and the condition in (4.6) isn’t satisfied for these estimators.

6. CONCLUSION

In this study, we have adapted some estimators to the stratified random sampling and we have proposed a family of exponential ratio type estimators which uses the information regarding the population proportion possessing certain attribute. The proposed estimators perform better than classical ratio estimator and adapted estimators known in sampling literature. Using suitable known parameters of auxiliary attributes in estimators give more efficient results in stratified random sampling.
