TOTAL		62,75		54,25		

^aThe error is the statistical error with one sigma confidence interval

^b Fold changes (FC) were given in log₂ base. * = greater than 1.5-fold increase and less than 2-fold increase, ** = between 2-fold and 4-fold increase, *** = greater than 4-fold increase. Negative FC values indicate when the FC value is high in SS.

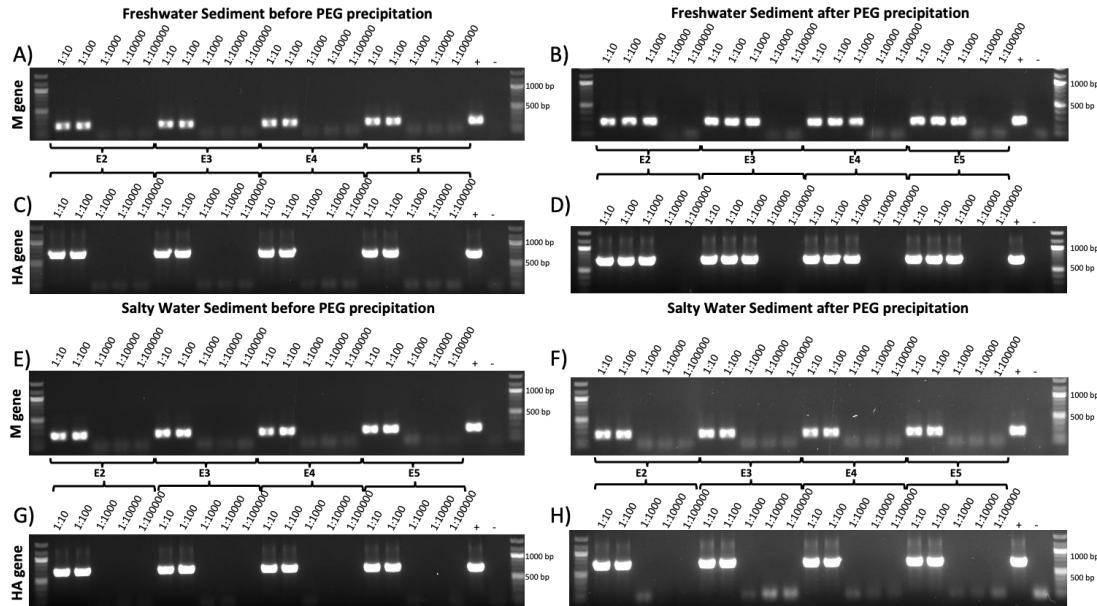

Figure S1. Confirmation of the presence of IAVs in four consecutive passages (E2-to-E5) via molecular methods. Viral genes were detected at 1:100 dilution ($4.5 \log_{10} \text{ EID}_{50}/\text{ml}$) in FS (A, C) and SS (E, G) before PEG precipitation according to the amplification of the specific region of M (A, E) and HA genes (C, G). PEG precipitation increased the efficiency of detection by 10-fold (1:1000 dilution; $3.5 \log_{10} \text{ EID}_{50}/\text{ml}$) for FS (B, D) based on the amplification of partial M (B) and partial HA genes (D). On the other hand, PEG precipitation did not affect the limit of detection based on the amplification of partial M (F) and partial HA (H) genes (1:100 dilution; $4.5 \log_{10} \text{ EID}_{50}/\text{ml}$) in SS. The viral RNA of H6N2 virus and nuclease-free water were used as a positive and negative control, respectively.
